

TREATISE

ON

DIFFERENTIAL EQUATIONS.

A TREATISE  
ON  
DIFFERENTIAL EQUATIONS

BY  
GEORGE BOOLE, F.R.S.  
PROFESSOR OF MATHEMATICS IN THE QUEEN'S UNIVERSITY, IRELAND,  
HONORARY MEMBER OF THE CAMBRIDGE PHILOSOPHICAL SOCIETY.

*FIFTH EDITION*

CHELSEA PUBLISHING COMPANY  
NEW YORK, N. Y.

THIS 5th EDITION OF BOOLE'S DIFFERENTIAL EQUATIONS  
CONSISTS OF THE 4th EDITION WITH THE 'SUPPLEMENTARY  
VOLUME' APPENDED AND PAGED CONSECUTIVELY WITH IT

LIBRARY OF CONGRESS CATALOGUE CARD NUMBER 59-9980

PRINTED IN THE UNITED STATES OF AMERICA

## PREFACE.

I HAVE endeavoured, in the following Treatise, to convey as complete an account of the present state of knowledge on the subject of Differential Equations, as was consistent with the idea of a work intended, primarily, for elementary instruction. It was my object, first of all, to meet the wants of those who had no previous acquaintance with the subject, but I also desired not quite to disappoint others who might seek for more advanced information. These distinct, but not inconsistent aims determined the plan of composition. The earlier sections of each chapter contain that kind of matter which has usually been thought suitable for the beginner, while the latter ones are devoted either to an account of recent discovery, or to the discussion of such deeper questions of principle as are likely to present themselves to the reflective student in connexion with the methods and processes of his previous course. An appendix to the table of contents will shew what portions of the work are regarded as sufficient for the less complete, but still not unconnected study of the subject.

The principles which I have kept in view in carrying out the above design, are the following :

1st, In the exposition of methods I have adhered as closely as possible to the historical order of their development.

I presume that few who have paid any attention to the history of the Mathematical Analysis, will doubt that it has been developed in a certain order, or that that order has been, to a great extent, necessary—being determined, either by steps of logical deduction, or by the successive introduction of new ideas and conceptions, when the time for their evolution had

arrived. And these are causes which operate in perfect harmony. Each new scientific conception gives occasion to new applications of deductive reasoning; but those applications may be only possible through the methods and the processes which belong to an earlier stage.

Thus, to take an illustration from the subject of the following work,—the solution of ordinary simultaneous differential equations properly precedes that of linear partial differential equations of the first order; and this, again, properly precedes that of partial differential equations of the first order which are not linear. And in this natural order were the theories of these subjects developed. Again, there exist large and very important classes of differential equations the solution of which depends on some process of successive reduction. Now such reduction seems to have been effected at first by a repeated change of variables; afterwards, and with greater generality, by a combination of such transformations with others involving differentiation; last of all, and with greatest generality, by symbolical methods. I think it necessary to direct attention to instances like these, because the indications which they afford appear to me to have been, in some works of great ability, overlooked, and because I wish to explain my motives for departing from the precedent thus set.

Now there is this reason for grounding the order of exposition upon the historical sequence of discovery, that by so doing we are most likely to present each new form of truth to the mind, precisely at that stage at which the mind is most fitted to receive it, or even, like that of the discoverer, to go forth to meet it. Of the many forms of false culture, a premature converse with abstractions is perhaps the most likely to prove fatal to the growth of a masculine vigour of intellect.

In accordance with the above principles I have reserved the exposition, and, with one unimportant exception, the application of symbolical methods to the end of the work. The

propriety of this course appears to me to be confirmed by an examination of the actual processes to which symbolical methods, as applied to differential equations, lead. Generally speaking, these methods present the solution of the proposed equation as dependent upon the performance of certain inverse operations. I have endeavoured to shew in Chap. XVI., that the expressions by which these inverse operations are symbolized are in reality a species of interrogations, admitting of answers, legitimate, but differing in species and character according to the nature of the transformations to which the expressions from which they are derived have been subjected. The solutions thus obtained may be particular or general,—they may be defective, wholly or partially, or complete or redundant, in those elements of a solution which are termed arbitrary. If defective, the question arises how the defect is to be supplied; if redundant, the more difficult question whether the redundancy is real or apparent, and in either case how it is to be dealt with, must be considered. And here the necessity of some prior acquaintance with the things themselves, rather than with the symbolic forms of their expression, must become apparent. The most accomplished in the use of symbols must sometimes throw aside his abstractions and resort to homelier methods for trial and verification—not doubting, in so doing, the truth which lies at the bottom of his symbolism, but distrusting his own powers.

The question of the true value and proper place of symbolical methods is undoubtedly of great importance. Their convenient simplicity—their condensed power—must ever constitute their first claim upon attention. I believe however that, in order to form a just estimate, we must consider them in another aspect, viz. as in some sort the visible manifestation of truths relating to the intimate and vital connexion of language with thought—truths of which it may be presumed that we do not yet see the entire scheme and con-

nexion. But, while this consideration vindicates to them a high position, it seems to me clearly to define that position. As discussions about words can never remove the difficulties that exist in things, so no skill in the use of those aids to thought which language furnishes can relieve us from the necessity of a prior and more direct study of the things which are the subjects of our reasonings. And the more exact, and the more complete, that study of things has been, the more likely shall we be to employ with advantage all instrumental aids and appliances.

But although I have, for the reasons above mentioned, treated of symbolical methods only in the latter chapters of the work, I trust that the exposition of them which is there given will repay the attention of the student. I have endeavoured to supply what appeared to me to be serious defects in their logic, and I have collected under them a large number of equations, nearly all of which are important,—from their connexion with physical science or for other reasons.

2ndly, I have endeavoured, more perhaps than it has been usual to do, to found the methods of solution of differential equations upon the study of the modes of their formation. In principle, this course is justified by a consideration of the real nature of inverse processes, the laws of which must be ultimately derived from those of the direct processes to which they stand related; in point of expediency it is recommended by the greater simplicity, and even in some instances by the greater generality, of the demonstrations to which it leads. I would refer particularly to the demonstration of Monge's method for the solution of partial differential equations of the second order given in Chap. xv.

With respect to the sources from which information has been drawn, it is proper to mention that, on questions relating to the theory of differential equations, my obligations are greatest to Lagrange, Jacobi, Cauchy, and, of living

writers, to Professor De Morgan. For methods and examples, a very large number of memoirs English and foreign have been consulted: these are, for the most part, acknowledged. At the same time it is right to add that, in almost every part of the work, I found it necessary to engage more or less in original investigation, and especially in those parts which relate to Riccati's equation, to integrating factors, to singular solutions, to the inverse problems of Geometry and Optics, to partial differential equations both of the first and second order, and, as has already been intimated, to symbolical methods. The demonstrations scattered through the work are also many of them new, at least in form.

In recent years much light has been thrown on certain classes of differential equations by the researches of Jacobi on the Calculus of Variations, and of the same great analyst, with Sir W. R. Hamilton and others, on Theoretical Dynamics. I have thought it more accordant with the design of an elementary treatise to endeavour to prepare the way for this order of inquiries than to enter systematically upon them. This object has been kept in view in the writing of various portions of the following work, and more particularly of that which relates to partial differential equations of the first order.

GEORGE BOOLE

QUEEN'S COLLEGE, CORK,  
*February, 1859*

## PREFACE TO THE SECOND EDITION.

IN composing his Treatise on Differential Equations Professor Boole found himself deeply interested in the subject to which his first labours as an original investigator had been devoted. In consequence he determined soon after the publication of the volume to continue his studies and researches with the design of ultimately reconstructing the Treatise on a more extensive scale. During the last six years of his life he worked steadily at this object; and he was about to send the first sheets of the new edition to the press when he was attacked by the illness which terminated in his sudden and lamented death.

His manuscripts were entrusted to me early in the present year. After careful consideration it seemed to me that the best plan to pursue was to reprint the original volume, and to collect into a supplementary volume the additional matter which had been prepared for enlarging the work. The propriety, I might almost say the necessity, of this course will be shewn more conveniently in the preface to the supplementary volume, which will soon be published.

The present volume then is a reprint of the original Treatise with changes and corrections, some of which were indicated in Professor Boole's interleaved copy, and some of which have been made on my own authority. The sheets have been carefully read by the Rev. J. Sephton, Fellow of St John's College, as well as by myself; and I trust that few misprints or errors will now be found in the volume.

I. TODHUNTER.

ST JOHN'S COLLEGE, CAMBRIDGE,  
*October, 1865.*

## PREFACE.

THE present volume contains all that Professor Boole wrote for the purpose of enlarging his *Treatise on Differential Equations*. Had he lived to publish the second edition he would doubtless have incorporated his more recent investigations with the original work, and it is therefore necessary to explain why another plan has been adopted.

In some cases Professor Boole had indicated that certain portions of the original work were to be omitted and their places supplied from the manuscripts; but on examination it appeared that in subsequent passages of the work there were references and allusions to the portions thus marked to be omitted which would not apply to the substituted matter. Thus in attempting to carry out the directions it would have been necessary to accept the responsibility of making many alterations, and consequently to incur the risk of failing in the attempt to improve the original form.

Moreover the *Treatise* had been for some time out of print, and the long delay which must have been caused by the labour of reconstruction would have produced serious inconvenience to students at Cambridge and elsewhere. Professor Boole himself was always especially anxious to consult

the advantage of students, and those who had the charge of his manuscripts were naturally inclined to adopt a course of which they believed he would himself have approved.

The design of reconstructing the Treatise was therefore abandoned; and it was resolved that the original volume should be reprinted, and that the manuscripts should be collected and published separately. This plan has the obvious recommendation of enabling those who are already familiar with the original work to turn their attention readily to the new investigations. It will be seen that many of the Chapters of the present volume may be regarded as independent essays or memoirs which lose nothing by being separated from the other volume; and indeed no indications had been left by Professor Boole of the place which such Chapters were to occupy in the enlarged edition.

I have printed all the unpublished matter relating to Differential Equations which I found among Professor Boole's papers. In a few cases it will be seen that an investigation is incomplete; such investigations have however been included in the volume, because I was unwilling that anything should be lost which so great a mathematician had written on a subject he had long and carefully studied.

I trust that no serious error will be found in the volume, and that any faults which may be detected will be excused on account of the nature and difficulty of the task that had to be performed. Many of the manuscripts had not been finally revised; some of them were very obscure and had to be carefully and laboriously copied for the press. In general the equations were not numbered, and thus only

blanks occurred in place of references; this circumstance often caused great trouble and perplexity: I hope however that a satisfactory result has been finally attained.

I may state for the benefit of those who are conversant with the first edition of the original work that the theorem which in the present volume is cited as contained in Chap. II. Art. 1 will be found in Chap. IV. Art. 2 of the first edition: the change was made by the direction of Professor Boole's interleaved copy. It was judged convenient to number the Chapters in the present volume in continuation of those in the original work.

All additions of my own are enclosed within square brackets. The sheets have been read by the Rev. J. Sephton, Fellow of St John's College, as well as by myself, and the volume is much indebted to his care and accuracy. Obvious mistakes in the manuscripts were of course corrected; thus, for example, the table at the end of the volume was calculated by Mr Sephton, because the table in the manuscript was rendered erroneous by the use of a wrong sign in a formula.

## LIST OF PROFESSOR BOOLE'S WRITINGS.

### *In the Philosophical Transactions.*

On a General Method in Analysis, 1844, pages 225...282.

On the Comparison of Transcendents, with certain applications to the Theory of Definite Integrals, 1857, pages 745...803.

On the Theory of Probabilities, 1862, pages 225...252.

On Simultaneous Differential Equations of the First Order in which the Number of the Variables exceeds by more than one the Number of the Equations, 1862, pages 437...454.

On the Differential Equations of Dynamics. A sequel to a Paper on Simultaneous Differential Equations, 1863, pages 485...501.

On the Differential Equations which determine the form of the Roots of Algebraic Equations, 1864, pages 733...755.

### *In the Transactions of the Royal Irish Academy.*

On the Analysis of Discontinuous Functions. Vol. 21, 1848, pages 124...139.

On a certain Multiple Definite Integral. Same Vol., pages 140...149.

### *In the Transactions of the Royal Society of Edinburgh.*

On the Application of the Theory of Probabilities to the Question of the Combination of Testimonies or Judgments. Vol. 21, 1857, pages 597...653.

### *In the Bulletin de l'Académie...de St Pétersbourg.*

Considérations sur la recherche des intégrales premières des équations différentielles partielles du second ordre, Vol. iv. 1862, pages 198...215. [See page 143 of the present volume.]

### *In Crelle's Journal für Mathematik.*

Ueber die partielle Differentialgleichung zweiter Ordnung  $Rr + Ss + Tt + U (s^2 - rt) = V$ . Vol. 61, pages 309...333.

*In the Cambridge Mathematical Journal.*

Researches on the Theory of Analytical Transformations, with a special application to the Reduction of the General Equation of the Second Order. Vol. 2, 1841, pages 64...73.

On Certain Theorems in the Calculus of Variations. Same Vol., pages 97...102.

On the Integration of Linear Differential Equations with Constant Coefficients. Same Vol., pages 114...119.

Analytical Geometry. Same Vol., pages 179...188.

Exposition of a General Theory of Linear Transformations. Vol. 3, 1843, pages 1...20, 106...119.

On the Transformation of Definite Integrals. Same Vol., pages 216...224.

Remarks on a Theorem of M. Catalan. Same Vol., pages 277...283.

On the Transformation of Multiple Integrals. Vol. 4, 1845, pages 20...28.

On the Inverse Calculus of Definite Integrals. Same Vol., pages 82...87.

Notes on Linear Transformations. Same Vol., pages 167...171.

On the Theory of Developments. Same Vol., pages 214...223.

*In the Cambridge and Dublin Mathematical Journal.*

On the Equation of Laplace's Functions. Vol. 1, 1846, pages 10...22.

On the Attraction of a Solid of Revolution on an External Point. Vol. 2, 1847, pages 1...7.

On a certain Symbolical Equation. Same Vol., pages 7...12.

On a General Transformation of any Quantitative Function. Vol. 3, 1848, pages 112...116.

The Calculus of Logic. Same Vol., pages 183...198.

On a General Theorem of Definite Integration. Vol. 4, 1849, pages 14...20.

On the Theory of Linear Transformations. Vol. 6, 1851, pages 87...106.

On the Reduction of the General Equation of the  $n^{\text{th}}$  Degree. Same Vol., pages 106...113.

Letter to the Editor of the Journal. Same Vol., pages 284, 285.

Proposed Question in the Theory of Probabilities. Same Vol., page 286.

On Reciprocal Methods in the Differential Calculus. Vol. 7, 1852, pages 156...166, and Vol. 8, 1853, pages 1...24.

*In the London, Edinburgh, and Dublin Philosophical Magazine...  
Third Series.*

Remarks on the Rev. B. Bronwin's Method for Differential Equations. Vol. 30, 1847, pages 6...8.

Note on a Class of Differential Equations. Same Vol., pages 96, 97.

Remarks on a Paper by the Rev. Brice Bronwin, On the Solution of a particular Differential Equation. Vol. 32, 1848, pages 413...418.

Remarks on a Paper by the Rev. Brice Bronwin, On the Solution of a Particular Differential Equation. Vol. 33, 1848, page 211.

Notes on Quaternions. Same Vol., pages 278...280.

*In the Fourth Series of the same Magazine.*

On the Theory of Probabilities, and in particular on Mitchell's Problem of the Distribution of the Fixed Stars. Vol. 1, 1851, pages 521...530.

Further Observations on the Theory of Probabilities. Vol. 2, 1851, pages 96...101.

An Account of the late John Walsh of Cork. In a letter from Professor Boole to Professor de Morgan. Same Vol., pages 348...358.

Solution of a Question in the Theory of Probabilities. Vol. 7, 1854, pages 29...32.

Reply to some Observations published by Mr Wilbraham in the Philosophical Magazine, Vol. 7, p. 465, on the Theory of Chances developed in Professor Boole's 'Laws of Thought.' Vol. 8, 1854, pages 87...91.

On the Conditions by which the Solutions of Questions in the Theory of Probabilities are limited. Same Vol., pages 91...98.

Further Observations relating to the Theory of Probabilities in reply to Mr Wilbraham. Same Vol., pages 175, 176.

On a General Method in the Theory of Probabilities. Same Vol., pages 431...444.

On certain Propositions in Algebra connected with the Theory of Probabilities. Vol. 9, 1855, pages 165...179.

On a Question in the Theory of Probabilities. By A. Cayley, Esq. [This paper embodies some observations by Professor Boole.] Vol. 23, 1862, pages 361...365.

On a Question in the Theory of Probabilities. Vol. 24, 1862, p. 80.

*Separate Publications.*

An Address on the Genius and Discoveries of Sir Isaac Newton. Lincoln, 1835.

The Right Use of Leisure. London, 1847.

The Mathematical Analysis of Logic, being an Essay towards a Calculus of Deductive Reasoning. Cambridge, 1847.

The Claims of Science. London, 1851.

An Investigation of the Laws of Thought, on which are founded the Mathematical Theories of Logic and Probabilities. London, 1854.

The Social Aspect of Intellectual Culture. An Address delivered in the Cork Athenæum.... Cork, 1855.

A Treatise on Differential Equations. Cambridge, 1859.

A Treatise on the Calculus of Finite Differences. Cambridge, 1860.

[This list contains all Professor Boole's writings which have fallen under the notice of the editor; it is possible that there may be a few omissions.]

# CONTENTS.

## CHAPTER I.

	PAGE
OF THE NATURE AND ORIGIN OF DIFFERENTIAL EQUATIONS	1

Definition, 2. Species, Order and Degree, 3. General Solution, Complete primitive, 6. Genesis of Differential equations, 8. How many of each order possible,—how many independent, 15. Criterion of derivation from a common primitive, 16. General form of equations thus related, 17. Geometrical illustrations, 18. Exercises, 20.

## CHAPTER II.

ON DIFFERENTIAL EQUATIONS OF THE FIRST ORDER AND DEGREE BETWEEN TWO VARIABLES . . .	23
--	----

General equation  $Mdx + Ndy = 0$ , 23. Complete primitive  $f(x, y) = c$ , 26. Geometrical illustration, 28. Various integrable cases, 29. Homogeneous equations, 34. Linear equations of first order, 38. Other forms, 40. Solution by development, 41. Exercises, 44.

## CHAPTER III.

EXACT DIFFERENTIAL EQUATIONS OF THE FIRST DEGREE	47
--	----

General criterion, 47. Mode of solution, 50. Practical simplifications, 52. Exercises, 53.

## CHAPTER IV.

	PAGE
ON THE INTEGRATING FACTORS OF THE DIFFERENTIAL EQUATION $Mdx + Ndy = 0$ .	55

Integrating factors always exist, 56. General form of integrating factors, 57. Special determinations for homogeneous equations and for equations of the form  $F_1(xy)ydx + F_2(xy)x dy = 0$ , 59—62. Exercises, 67.

## CHAPTER V.

ON THE GENERAL DETERMINATION OF THE INTEGRATING FACTORS OF THE EQUATION $Mdx + Ndy = 0$	69
--	----

Partial differential equation for integrating factors, 69. Solution when the integrating factor is a function of  $x$ , 70—of  $y$ , 71—of  $xy$ , 72. When homogeneous, 74—76. More general application, 82. Solution of  $P_1dx + P_2dy + Q(xdy - ydx) = 0$ , 84. Jacobi's equation, 85. Euler's method, 86. Exercises, 88.

## CHAPTER VI.

ON SOME REMARKABLE EQUATIONS OF THE FIRST ORDER AND DEGREE	91
---	----

Riccati's equation  $\frac{du}{dx} + bu^2 = cx^m$ , 91.  $x\frac{dy}{dx} - ay + by^2 = cx^n$ , 92. Solution by continued fractions, 96, 97. Riccati's equation made linear, 103. Euler's equation, 104. Theorem of development, 107. Exercises, 110.

## CHAPTER VII.

ON DIFFERENTIAL EQUATIONS OF THE FIRST ORDER, BUT NOT OF THE FIRST DEGREE	113
--	-----

Typical form, 113. Theory of its solution, 115. Relation of complete primitive to particular integrals, &c., 117. Special methods, 121. One variable only involved, 122.  $x\phi(p) + y\psi(p) = \chi(p)$ , 124. Clairaut's equation, *ib.* Singular solutions, 125. Homogeneous equations, 128. Equations solvable by differentiation, 131. Transformations, 134. Exercises, 136.

# CHAPTER VIII.

	PAGE
ON THE SINGULAR SOLUTIONS OF DIFFERENTIAL EQUATIONS OF THE FIRST ORDER . . . . .	139

Primary definition—positive and negative marks, 139, 140. Derivation of the singular solution from the complete primitive, 141. General theorem, 148. Geometrical interpretation, 152. Derivation of the singular solution from the differential equation, 153. More general definition of singular solution, 163. Distinction of species, *ib.* General theorem, 164. Review of prior methods, 174. Properties of singular solutions, 177. Exercises, 182.

# CHAPTER IX.

ON DIFFERENTIAL EQUATIONS OF AN ORDER HIGHER THAN THE FIRST . . . . .	187
--	-----

Relation to complete primitive, 187. Solution by development, 189. Linear equations, 192—199. General rule when the second member is 0, 200. Second member a function of  $x$ ,—Variation of parameters, *ib.* Dependent class, 203. Properties of linear equations, 204. Analogy with Algebraic equations, 206. Exercises, 207.

# CHAPTER X.

EQUATIONS OF AN ORDER HIGHER THAN THE FIRST, CONTINUED	209
--	-----

One variable wanting, 209. One differential coefficient present, 211.  $\frac{d^n y}{dx^n} = f\left(\frac{d^{n-1} y}{dx^{n-1}}\right)$ , 212.  $\frac{d^n y}{dx^n} = f\left(\frac{d^{n-2} y}{dx^{n-2}}\right)$ , 214. Homogeneous equations, 215. Exact equations, 222. Miscellaneous methods and examples, 226. Singular integrals, 229. Exercises, 234.

# CHAPTER XI.

GEOMETRICAL APPLICATIONS . . . . .	238
------------------------------------	-----

Different problems, 239—244. Trajectories, 245. Curves of Pursuit, 251. Solution of a differential equation, 254. Involution, 256. Inverse problem of caustics, 258—263. Direct problem, 259. Intrinsic equation of a curve, 263. Exercises, 269.

## CHAPTER XII.

	PAGE
ORDINARY DIFFERENTIAL EQUATIONS WITH MORE THAN TWO VARIABLES . . . . .	272
Meaning of $Pdx + Qdy + Rdz = 0$ , 272. Condition of derivation from a single primitive, 275. Solution, 276. General rule and ex- amples, 279. Homogeneous equations, 281. Integrating fac- tors, 282. Equations not derivable from a single primitive, 283. More than three variables, 286. Equations of an order higher than the first, 289. Exercises, 291.	

## CHAPTER XIII.

SIMULTANEOUS DIFFERENTIAL EQUATIONS . . . . .	292
Meaning of a determinate system, 292. General theory of simulta- neous equations of the first order and degree, 293—307. Systems of two equations, 294. Of more than two, 298. Linear equations with constant coefficients, 300. Equations of an order higher than the first, 307. Exercises, 316.	

## CHAPTER XIV.

OF PARTIAL DIFFERENTIAL EQUATIONS . . . . .	319
Nature, 319. Primary modes of genesis, 321. Solution when all the differential coefficients have reference to only one of the inde- pendent variables, 322. Linear equations of first order, 324. Their genesis, 325. Their solution, 329. Non-linear equations of the first order, 335. Complete primitive, general primitive, and singular solution, 339. Sufficiency of a single complete pri- mitive, 345. Singular solutions, 346. Geometrical applica- tions, 347. Symmetrical and more general solution of equations of the first order, 350. Exercises, 358.	

## CHAPTER XV.

PARTIAL DIFFERENTIAL EQUATIONS OF THE SECOND ORDER	361
The equation $Rr + Ss + Tt = V$ , 361. Condition of its admitting a first integral of the form $u = f(v)$ , 362. Deduction of such integral when possible, 364. Relations of first integrals, 366. General rule, 369. Miscellaneous theorems. Poisson's method, 375. Duality, 376. Legendre's Transformation, 379. Exercises, 380.	

## CHAPTER XVI.

	PAGE
SYMBOLICAL METHODS . . .	381

Laws of direct expressions, 381—384. Inverse forms, 385. Linear equations with constant coefficients, 388. Forms purely symbolical, 398. Equations solvable by means of the properties of homogeneous functions, 403. The method generalized, 406. Exercises, 410.

## CHAPTER XVII.

SYMBOLICAL METHODS, CONTINUED . . .	412
-------------------------------------	-----

Symbolical form of differential equations with variable coefficients, 412. Finite solution, 415—436. Reduction of binomial equations, 418. Pfaff's equation, 430. Equations not binomial, 432. Solution by series, 437. Evaluation of series, 441. Generalization, 446. Theorem of development, 447. Laplace's reduction of partial differential equations, 450. Miscellaneous notices, 454. Exercises, 457.

## CHAPTER XVIII.

SOLUTION OF LINEAR DIFFERENTIAL EQUATIONS BY DEFINITE INTEGRALS . . .	461
--	-----

Laplace's method, 461. Partial differential equations, 475. Parseval's theorem, 477. Solution by Fourier's theorem, 478. Miscellaneous exercises, 481.

*The following portions of the work are recommended to beginners.*

Chap. I. Arts. 1—8, 11. Chap. II. Arts. 1—11. Chap. III. Chap. IV. Arts. 1—9. Chap. V. Arts. 1—4. Chap. VI. Arts. 1—10. Chap. VII. Arts. 1—8. Chap. VIII. Arts. 1—7. Chap. IX. Arts. 1, 3—12. Chap. X. Arts. 1—3. Chap. XI. Arts. 1—7. Chap. XII. Arts. 1—8. Chap. XIII. Chap. XIV. Arts. 1—12. Chap. XV. Arts. 1—8. Chap. XVI. Arts. 1—8. Chap. XVII. Arts. 1—12. Chap. XVIII. Arts. 1—8.

# DIFFERENTIAL EQUATIONS.

## CHAPTER I.

### OF THE NATURE AND ORIGIN OF DIFFERENTIAL EQUATIONS.

#### 1. WHAT is meant by a differential equation?

To answer this question we must revert to the fundamental conceptions of the Differential Calculus.

The Differential Calculus contemplates quantity as subject to variation; and variation as capable of being measured. In comparing any two variable quantities  $x$  and  $y$  connected by a known relation, e.g. the ordinate and abscissa of a given curve, it defines the rate of variation of the one,  $y$ , as referred to that of the other,  $x$ , by means of the fundamental conception of a limit; it expresses that ratio by a differential coefficient  $\frac{dy}{dx}$ ; and of that differential coefficient it shews how to determine the varying magnitude or value. Or, again, considering  $\frac{dy}{dx}$  as a new variable, it seeks to determine the rate of its variation as referred to the same fixed standard, the variation of  $x$ , by means of a second differential coefficient  $\frac{d^2y}{dx^2}$ , and so on. But in all its applications, as well as in its theory and its processes, the primitive relation between the variables  $x$  and  $y$  is supposed to be *known*.

In the Integral Calculus, on the other hand, it is the relation among the primitive variables,  $x$ ,  $y$ , &c. which is *sought*. In that branch of the Integral Calculus with which the student

is supposed to be already familiar, the differential coefficient  $\frac{dy}{dx}$  being given in terms of the independent variable  $x$ , it is proposed to determine the most general relation between  $y$  and  $x$ . Expressing the *given* relation in the form

$$\frac{dy}{dx} = \phi(x) \dots\dots\dots(1),$$

the relation *sought* is exhibited in the form

$$y = \int \phi(x) dx + c.$$

In (1) we have a particular example of an equation in the expression of which a differential coefficient is involved. But instead of having as in that example  $\frac{dy}{dx}$  expressed in terms of  $x$ , we might have that differential coefficient expressed in terms of  $y$ , or in terms of  $x$  and  $y$ . Or we might have an equation in which differential coefficients of a higher order,  $\frac{d^2y}{dx^2}$ ,  $\frac{d^3y}{dx^3}$ , &c., were involved, with or without the primitive variables. All these including (1) are examples of differential equations. The *essential* character consists in the presence of differential coefficients.

The equations

$$\frac{d^2y}{dx^2} + 2 \frac{dy}{dx} = 0 \dots\dots\dots(2),$$

$$x^2 \frac{d^2y}{dx^2} + x \frac{dy}{dx} + y = \sin x \dots\dots\dots(3),$$

are seen to be differential equations, the latter of which contains, while the former does not contain, the primitive variables.

And thus we are led to the following definition.

DEF. A *differential equation* is an expressed relation involving differential coefficients, with or without the primitive variables from which those differential coefficients are derived.

That which gives to the study of differential equations its peculiar value, is the circumstance that many of the most important conceptions of Geometry and Mechanics can only be realized in thought by means of the fundamental conception of the limit. When such is the case, the only adequate expression of those conceptions in language is through the medium of differential coefficients,—the only adequate expression of the truths and relations of which they are the subjects is in the form of differential equations.

### *Species, Order and Degree.*

2. The species of differential equations are determined either by the mode in which differential coefficients enter into their composition, or by the nature of the differential coefficients themselves. We may thus distinguish two great primary classes of differential equations, viz.:

1st. Ordinary differential equations, or those in which all the differential coefficients involved have reference to a single independent variable.

2ndly. Partial differential equations, characterized by the presence of *partial* differential coefficients, and therefore indicating the existence of two or more independent variables with respect to which those differential coefficients have been formed.

Thus an equation such as (2) or (3), involving no other differential coefficients than  $\frac{dy}{dx}$ ,  $\frac{d^2y}{dx^2}$ , &c. is an ordinary differential equation, in which  $x$  is the independent,  $y$  the dependent variable. An equation involving  $\frac{dz}{dx}$  and  $\frac{dz}{dy}$  would, on the contrary, be a partial differential equation, having  $z$  for its dependent,  $x$  and  $y$  for its independent variables. The equation  $x \frac{dz}{dx} + y \frac{dz}{dy} = z$  is a partial differential equation.

The present chapter will be chiefly devoted to the consideration of that class of ordinary differential equations in

which there exists a single independent variable  $x$ , a single dependent variable  $y$ , and one or more of the differential coefficients of  $y$  taken with respect to  $x$ ; the presence of the last element only, viz. the differential coefficient, being essential (Art. 1).

The two following equations, in addition to those already given, will exemplify some of the chief varieties of the species under consideration:

$$\frac{y - x \frac{dy}{dx}}{\sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}}} = c \dots\dots\dots (4),$$

$$\frac{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}^{\frac{3}{2}}}{\frac{d^2y}{dx^2}} = mx \dots\dots\dots (5).$$

In (4) the independent variable  $x$ , the dependent variable  $y$ , and the differential coefficient  $\frac{dy}{dx}$  are all involved; but, while in the previous examples  $\frac{dy}{dx}$  appears only in the first degree, in the present one it appears in the second degree and under a radical sign. In (5) we meet with the second differential coefficient  $\frac{d^2y}{dx^2}$  in addition to the first differential coefficient  $\frac{dy}{dx}$  and the independent variable  $x$ .

The typical or general form of a differential equation of the species just described is

$$f\left(x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots \frac{d^ny}{dx^n}\right) = 0 \dots\dots\dots (6),$$

with the condition, already referred to, that one at least of the differential coefficients must explicitly present itself. All the above equations may at once be referred to the typical form by transposition of their second member.

3. Differential Equations are ranked in *order* and *degree* according to the following principles.

1st. The order of a differential equation is the same as the order of the highest differential coefficient which it contains.

2ndly. The degree of a differential equation is the same as the degree to which the differential coefficient which marks its order is raised, that coefficient being supposed to enter into the equation in a rational form.

Thus the equation

$$\left(\frac{dy}{dx}\right)^2 + a\frac{dy}{dx} = b,$$

is of the first order and of the second degree.

The equation

$$\frac{d^2y}{dx^2} + a\frac{dy}{dx} + by^2 = c,$$

is of the second order and of the first degree.

The equation

$$\frac{dy}{dx} = \sqrt{\left(y - x\frac{dy}{dx}\right)} \dots\dots\dots(7),$$

reduced to the rational form

$$\left(\frac{dy}{dx}\right)^2 + x\frac{dy}{dx} - y = 0 \dots\dots\dots(8),$$

is seen to be of the first order and second degree.

The ground of the preference which is to be given to rational forms in the expression and in the classification of differential equations is, that a rational form is at the same time the most *general* form of which an equation is susceptible. Thus (8) includes both the equations which would be formed by giving different signs to the radical in (7).

The typical form of an ordinary differential equation of the first order is evidently

$$f\left(x, y, \frac{dy}{dx}\right) = 0 \dots\dots\dots(9).$$

4. When a differential equation is capable of being expressed in the form

$$\frac{d^n y}{dx^n} + X_1 \frac{d^{n-1} y}{dx^{n-1}} + X_2 \frac{d^{n-2} y}{dx^{n-2}} \dots + X_n y = X \dots\dots\dots(10),$$

in which the coefficients  $X_1, X_2, \dots, X_n$  and the second member  $X$  are either constant quantities or functions of the independent variable  $x$  only, the equation is said to be linear. Equations (1), (2) and (3) are thus seen to be linear, but (4) and (5) are not linear. If we refer (3), after dividing both members by  $x^2$ , to the general form (10), we have

$$n = 2, X_1 = \frac{1}{x}, X_2 = \frac{1}{x^2}, X = \frac{\sin x}{x^2}.$$

When the coefficients  $X_1, X_2$ , &c. in the first member of a linear differential equation referred to the above general type are constant quantities, the equation is defined as a linear differential equation with constant coefficients. When those coefficients are not all constant it is defined as a linear differential equation with variable coefficients. The distinction is illustrated in the following examples :

$$\frac{d^3 y}{dx^3} - 2 \frac{d^2 y}{dx^2} + 5 \frac{dy}{dx} - 8y = \sin x,$$

$$(1 - x^2) \frac{d^2 y}{dx^2} - x \frac{dy}{dx} + 4y = \cos x,$$

the former of which is a linear differential equation with constant coefficients, while the latter would be described as a linear differential equation with variable coefficients.

*Meaning of the terms 'general solution,' 'complete primitive.'*

5. In all differential equations there is, as has been seen, an implied reference to some relation among variable quantities dependent and independent; such reference being established through the medium of differential coefficients. Now the chief object of the study of differential equations is to enable us to

determine whenever it is possible, and in the most general manner which is possible, such implied relation among the primitive variables. That relation, when discovered, is, by the adoption of a term primarily applicable to the mode or process of its discovery, called the *solution* of the equation.

Thus if the given equation be

$$x \frac{dy}{dx} + y = \cos x \dots \dots \dots (11),$$

the following process of solution may be adopted. Multiplying by  $dx$ , we have

$$x dy + y dx = \cos x dx,$$

and integrating, since each member is an exact differential,

$$xy = \sin x + c \dots \dots \dots (12).$$

The result is termed the solution, or, still more definitely, the *general* solution of the equation. It involves an arbitrary constant,  $c$ , by giving particular values to which a series of particular solutions is obtained. The equations

$$xy = \sin x,$$

$$xy = \sin x + 1,$$

are particular solutions of the given differential equation.

The term solution is still employed, even when the integration necessary in order to obtain in a finite and explicit form the relation between the variables cannot be effected. Thus if we had the differential equation,

$$x \frac{dy}{dx} - y - x e^x = 0 \dots \dots \dots (13),$$

we should thence derive in succession

$$\frac{x dy - y dx}{x^2} = \frac{e^x dx}{x};$$

$$\frac{y}{x} = \int \frac{e^x dx}{x} + c \dots \dots \dots (14),$$

and the last result is called the solution of the given equation, although it involves an integration which cannot be performed in finite terms.

The relation among the variables which constitutes the general solution of a differential equation, as above described, is also termed its *complete primitive*. The relation (14) involving the arbitrary constant  $c$  is virtually the complete primitive of the differential equation (13). It will be observed that the terms 'general solution' and 'complete primitive,' though applied to a common object, have relation to distinct processes and to a distinct order of thought. In the strict application of the former term we contemplate the differential equation as prior in the order of thought, and the explicit relation among the variables as thence deduced by a process of solution; while in the strict use of the latter term the order both of thought and of process is reversed.

### *Genesis of Differential Equations.*

6. The theory of the genesis of differential equations from their primitives is to a certain extent explained in treatises on the Differential Calculus, but there are some points of great importance relating to the connexion of differential equations thus derived, not only with their primitive, but with each other, which need a distinct elucidation.

Suppose that the complete primitive expresses a relation between  $x$ ,  $y$  and an arbitrary constant  $c$ . Differentiating on the supposition that  $x$  is the independent variable, we obtain a new equation which must involve  $\frac{dy}{dx}$ , and which may involve any or all of the quantities  $x$ ,  $y$  and  $c$ . If it do not involve  $c$ , it will constitute the differential equation of the first order corresponding to the given primitive. If it involve  $c$ , then the elimination of  $c$  between it and the primitive will lead to the differential equation in question.

Thus if the complete primitive be

$$y = cx \dots\dots\dots(1),$$

we have on differentiation,

$$\frac{dy}{dx} = c \dots\dots\dots(2),$$

and, eliminating the constant  $c$ ,

$$y = x \frac{dy}{dx} \dots\dots\dots(3),$$

the differential equation of the first order of which (1) is the complete primitive.

That primitive might have been so prepared as to lead to the same final equation by mere differentiation. Thus, reducing the primitive to the form

$$\frac{y}{x} = c,$$

we have on differentiating and clearing the result of fractions,

$$x \frac{dy}{dx} - y = 0,$$

which agrees with (3). And generally, if a primitive involving an arbitrary constant  $c$  be reduced to the form  $\phi(x, y) = c$ , the corresponding differential equation will be obtained by mere differentiation and removal of irrelevant factors, i.e. of factors which do not contain  $\frac{dy}{dx}$ , and do not therefore affect

the relation in which  $\frac{dy}{dx}$  stands to  $x$  and  $y$ . For it is in that relation, as already intimated, Art. 2, that the *essential* character of the differential equation consists.

It is to be observed that when the differentiation of a primitive involving an arbitrary constant  $c$  does not of itself cause that constant to disappear, the result to which it leads is still a differential equation, only not that differential equation of which the equation given constitutes the *complete* primitive. Thus, while the complete primitive of (3) is (1), that of (2) is  $y = cx + c'$ ,  $c'$  being now the arbitrary constant,—arbitrary as being independent of anything contained in the differential

equation. Indeed when we consider  $\frac{dy}{dx} = c$  as the differential equation, the constant  $c$ , as entering into its complete primitive,

$$y = cx + c',$$

is not arbitrary, the value which it bears in the primitive being determined by that which it bears in the differential equation.

As another illustration of the same theory, the equation  $y = c\epsilon^{ax}$  as complete primitive gives rise to the differential equation of the first order

$$\frac{dy}{dx} - ay = 0,$$

while the equation *immediately* derived from it by differentiation, viz.  $\frac{dy}{dx} = ca\epsilon^{ax}$ , has for its complete primitive  $y = c\epsilon^{ax} + c'$ . To the last mentioned differential equation,  $y = c\epsilon^{ax}$  stands in the relation of a particular primitive.

### *Second and Higher Orders.*

7. It is shewn in the previous section that from an equation containing  $x$  and  $y$  with an arbitrary constant  $c$ , we can by differentiation, and elimination (if necessary) of that constant, obtain the differential equation of the first order, of which the given equation constitutes the complete primitive.

In like manner an equation connecting  $x$ ,  $y$ , and two arbitrary constants being given, if we differentiate twice, and eliminate, should they not have already disappeared, the arbitrary constants, we shall arrive at a differential equation of the second order free from both the constants in question, and of which the given equation constitutes the complete primitive.

Thus, if we take as the primitive equation

$$y = ax^2 + bx \dots \dots \dots (4),$$

we find on differentiation

$$\frac{dy}{dx} = 2ax + b \dots \dots \dots (5),$$

and, eliminating  $b$  between these equations,

$$y = x \frac{dy}{dx} - ax^2 \dots \dots \dots (6),$$

a differential equation of the first order free from the constant  $b$ . Differentiating this equation we have

$$x \frac{d^2y}{dx^2} = 2ax,$$

and, eliminating  $a$  between the last two equations,

$$x^2 \frac{d^2y}{dx^2} - 2x \frac{dy}{dx} + 2y = 0 \dots \dots \dots (7),$$

a differential equation of the second order free from both  $a$  and  $b$ .

In the above example the constant  $b$  was eliminated after the first differentiation, and the constant  $a$  after the second. But the same final result would have been arrived at if the order of the eliminations had been reversed. Thus, if  $a$  be eliminated between (4) and (5), we shall have

$$x \frac{dy}{dx} + bx - 2y = 0,$$

a differential equation of the first order, different in form from (6), and involving  $b$  instead of  $a$ . But on differentiating this equation and eliminating  $b$ , we shall arrive at the same final equation of the second order (7).

And generally *the order in which the constants are eliminated does not affect the form of the final differential equation.*

Now a little consideration will shew that this is necessarily the case. We are to remember that the generality which the primitive derives from the presence of its arbitrary constants consists only in this, that it is thus made to stand as the

representative of an infinite number of particular equations, in each of which these constants receive particular and definite values. If in any one of the equations thus particularized we further give to  $x$  a definite value, definite values will also result for  $y$ ,  $\frac{dy}{dx}$ ,  $\frac{d^2y}{dx^2}$ , &c. Thus to a given abscissa of a given curve, i.e. of a curve determined as to its *species* by the form of its equation, and as to its *elements* by the values of the constants in that equation, correspond only definite values of the ordinate  $y$  determining the corresponding points of the curve, definite values of  $\frac{dy}{dx}$  determining the inclination of the tangents at such points to the axis of  $x$ , and definite values of  $\frac{d^2y}{dx^2}$  determining, in conjunction with the former, the measure of curvature at the same points. In other words, the species of the curve as defined by an equation of the form  $\phi(x, y, a, b) = 0$  being fixed, the values of  $y$ ,  $\frac{dy}{dx}$ ,  $\frac{d^2y}{dx^2}$  have a fixed dependence on those of  $a$ ,  $b$  and  $x$ .

And hence the equation  $\phi(x, y, a, b) = 0$  being given, any processes of differentiation, elimination, &c. applied thereto can only serve, either 1st, to bring out or manifest the dependence above referred to, or 2ndly, to modify the accidental form of its expression; but in no sense to *create* such dependence or affect its real nature. Now this dependence of  $y$ ,  $\frac{dy}{dx}$ ,  $\frac{d^2y}{dx^2}$  upon  $a$ ,  $b$ , and  $x$ , involves the existence of three equations among six quantities. Therefore the elimination which thus becomes possible of two of those quantities,  $a$ ,  $b$ , must leave a single final relation between the remaining four,  $x$ ,  $y$ ,  $\frac{dy}{dx}$ ,  $\frac{d^2y}{dx^2}$ . And this is the differential equation in question.

As another example, let us eliminate the arbitrary constants  $c$  and  $c'$  from the equation

$$y = c\epsilon^{ax} + c'\epsilon^{bx} \dots\dots\dots (8).$$

Differentiating we have

$$\frac{dy}{dx} = ac\epsilon^{ax} + bc'\epsilon^{bx} \dots\dots\dots(9).$$

To eliminate  $c$  subtract from this equation the primitive (8) multiplied by  $a$ ; we have

$$\frac{dy}{dx} - ay = (b - a) c' \epsilon^{bx} \dots\dots\dots(10).$$

Again, differentiating

$$\frac{d^2y}{dx^2} - a \frac{dy}{dx} = b(b - a) c' \epsilon^{bx},$$

and (to eliminate  $c'$ ) subtracting from this the previous equation multiplied by  $b$ , we have

$$\frac{d^2y}{dx^2} - (a + b) \frac{dy}{dx} + aby = 0 \dots\dots\dots(11),$$

the differential equation of the second order required.

If we had first eliminated  $c'$  we should in the place of (10) have obtained the equation

$$\frac{dy}{dx} - by = (a - b) c \epsilon^{ax} \dots\dots\dots(12).$$

Differentiating this and eliminating  $c$  we again obtain the same final result (11).

That result is a differential equation of the second order, and (8), involving both the arbitrary constants  $c$  and  $c'$ , is its complete primitive. The intermediate equations (10) and (12), each of which contains one of the arbitrary constants, and from each of which, by the elimination of that constant, the final differential equation may be derived, are its *first integrals*. As the term primitive has reference to the direct processes of differentiation, &c. by which a differential equation is formed, the term integral has reference to the inverse process of integration by which we reascend from a differential equation to its primitive. Considered with reference to these processes the primitive is sometimes termed the *final integral*.

It has been shewn that the order of succession in which arbitrary constants are eliminated is indifferent. It may be added, and upon the same ground, that the elimination may be simultaneous. If we write the primitive (8) in the form

$$y - c\epsilon^{ax} - c'\epsilon^{bx} = 0,$$

and differentiate it twice, we have

$$\frac{dy}{dx} - ac\epsilon^{ax} - bc'\epsilon^{bx} = 0,$$

$$\frac{d^2y}{dx^2} - a^2c\epsilon^{ax} - b^2c'\epsilon^{bx} = 0,$$

and, from the above system of three equations eliminating the constants  $c$  and  $c'$  by the method of cross-multiplication, we again arrive at the final differential equation of the second order (11).

8. The above examples prepare us for the general statement of the theory of the genesis of differential equations. Let  $F(x, y, c_1, c_2, \dots, c_n) = 0$  be a primitive equation between  $x$  and  $y$  involving  $n$  arbitrary constants  $c_1, c_2, \dots, c_n$ . Differentiating with respect to  $x$ , and regarding  $y$  as a function of  $x$ , we obtain directly, or by elimination of  $c_1$ , an equation of the first order of the form

$$\phi_1 \left( x, y, \frac{dy}{dx}, c_2, c_3, \dots, c_n \right) = 0.$$

Differentiating this equation with respect to  $x$ , and regarding  $y$  and  $\frac{dy}{dx}$  as functions of that quantity, we obtain directly, or by elimination of  $c_2$ , an equation of the second order of the general form

$$\phi_2 \left( x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, c_3, c_4, \dots, c_n \right) = 0.$$

Continuing the process, we arrive at a final result of the form

$$\phi_n \left( x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots, \frac{d^ny}{dx^n} \right) = 0.$$

Now this is the type of an ordinary differential equation of the  $n^{\text{th}}$  order, (6), Art. 2.

As, in the above process of differentiation and elimination, we might have begun by eliminating any other of the constants instead of  $c_1$ , it follows that to a primitive containing  $n$  arbitrary constants there belong  $n$  differential equations of the first order, each involving  $n - 1$  arbitrary constants. But as those differential equations are all formed by mere processes of elimination from *two* equations, viz. from the primitive and its first derived equation, *two* only of them are independent. Again, as the differential equations of the second order are formed by eliminating two of the constants  $c_1, c_2, \dots c_n$ , and as from  $n$  constants,  $n \frac{n-1}{2}$  combinations of two constants can be selected, it is seen that there will exist  $n \frac{n-1}{2}$  differential equations of the second order, each containing  $n - 2$  arbitrary constants. Of these equations three only will however be independent, the whole system being derived actually or virtually from the primitive and its first and second derived equations;—actually if we differentiate twice before eliminating; virtually if each differentiation is followed by the elimination of a constant.

This process of deduction continued leads to the following general theorems, viz.:

1st. *To a given primitive involving  $x, y$ , and  $n$  arbitrary constants belong  $\frac{n(n-1)(n-2) \dots (n-r+1)}{1 \cdot 2 \dots r}$  differential equations of the  $r^{\text{th}}$  order ( $r$  being any whole number less than  $n$ ), each involving  $n - r$  arbitrary constants, but of those equations  $r + 1$  only will be independent.*

2nd. *There will exist one differential equation of the  $n^{\text{th}}$  order free from arbitrary constants.*

The converse of the latter truth, viz. that a differential equation of the  $n^{\text{th}}$  order implies the existence of a complete primitive involving  $n$  arbitrary constants, will be established in a future page. [See page 187.]

*Criterion of derivation from a common primitive.*

9. It is established in Art. 7, 1st, that from a primitive equation involving two arbitrary constants arise two differential equations of the first order, each involving one of those constants; 2ndly, that each of these differential equations of the first order gives rise to the same differential equation of the second order, of which the original equation constitutes the complete primitive or final integral.

The second of the properties above noted constitutes a criterion by which it may be determined whether two differential equations of the first order, each involving an arbitrary constant, originate from the same primitive. We must differentiate each equation, and then eliminate its arbitrary constant. If the two results agree as differential equations of the second order, i.e. if they give the same value of  $\frac{d^2y}{dx^2}$  as a function of  $x$ ,  $y$ , and  $\frac{dy}{dx}$ , the differential equations of the first order must have originated in the same primitive. Furthermore, that primitive will be obtained by eliminating  $\frac{dy}{dx}$  between the two differential equations given.

Ex. The differential equations of the first order

$$y \frac{dy}{dx} - ax = 0 \dots\dots\dots(1),$$

$$y^2 - xy \frac{dy}{dx} = b \dots\dots\dots(2),$$

are both derived from the same primitive. Each of them leads on differentiation and elimination of its arbitrary constant to the differential equation of the second order,

$$xy \frac{d^2y}{dx^2} + x \left( \frac{dy}{dx} \right)^2 - y \frac{dy}{dx} = 0 \dots\dots\dots(3).$$

The primitive, found by eliminating  $\frac{dy}{dx}$  from the given equations, is

$$y^2 - ax^2 = b \dots \dots \dots (4),$$

$a$  and  $b$  being arbitrary constants.

10. The differential equations of the first order which constitute the first integrals (Art. 7) of a differential equation of the second order (as, in the above example, (1) and (2) are first integrals of (3)), may by algebraic solution be reduced to the forms

$$\phi \left( x, y, \frac{dy}{dx} \right) = a \dots \dots \dots (5),$$

$$\psi \left( x, y, \frac{dy}{dx} \right) = b \dots \dots \dots (6).$$

Now a function of the arbitrary constants  $a$  and  $b$ , as  $\Phi(a, b)$ , is itself an arbitrary constant, and may be represented by  $c$ . Hence any equation of the form

$$\Phi \left\{ \phi \left( x, y, \frac{dy}{dx} \right), \psi \left( x, y, \frac{dy}{dx} \right) \right\} = c \dots \dots \dots (7)$$

would, equally with (5) and (6), constitute a first integral of the supposed equation of the second order. It is evident that (7) is the general type of all such first integrals.

Thus the type of the first integrals of (3) would be

$$\Phi \left( \frac{y}{x} \frac{dy}{dx}, y^2 - xy \frac{dy}{dx} \right) = c.$$

But any two first integrals included under this type and independent of each other would lead us, as is obvious, to the same final integral (4), either under its actual or under an equivalent form.

While therefore, viewed as an independent system, the first integrals of a differential equation of the second order are but

two, it is formally more correct to regard them as infinite in number, but as so related that any two of them which are independent contain by implication all the rest.

Such considerations are easily extended to differential equations of the higher orders.

### *Geometrical illustrations.*

11. Geometry, by its peculiar conceptions of direction, tangency, and curvature, all developed out of the primary conception of the limit, Art. 1, throws much light on the nature of differential equations.

As the simplest illustration let the equation of a straight line

$$y = ax + b \dots\dots\dots(1)$$

be taken as the complete primitive,  $a$  and  $b$  being arbitrary constants,

Differentiating, we have

$$\frac{dy}{dx} = a \dots\dots\dots(2).$$

Eliminating  $a$ , we find

$$y - x \frac{dy}{dx} = b \dots\dots\dots(3),$$

and again differentiating

$$\frac{d^2y}{dx^2} = 0 \dots\dots\dots(4).$$

Of these equations, (4), which is free from arbitrary constants, is the general differential equation of the second order of a straight line; and (2) and (3), each of which contains one of the original arbitrary constants, are the two differential equations of the first order. Moreover, each of these differential equations expresses some general property of the straight line—(2), that its inclination to the axis is uniform; (3), that any intercept, parallel to the axis of  $y$ , between the

straight line and a parallel to it through the origin will be of constant length; (4), that a straight line is nowhere either convex or concave;—and this property, which does not involve, in the same definite manner as the others do, the considerations of distance and of angular magnitude, is evidently the most absolute of the three.

The equation of the circle is

$$(x - a)^2 + (y - b)^2 = r^2 \dots\dots\dots(5),$$

and if we regard  $a$  and  $b$  as arbitrary constants the corresponding differential equation of the second order will be

$$\frac{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}^{\frac{3}{2}}}{\frac{d^2y}{dx^2}} = r \dots\dots\dots(6),$$

expressing the property that the radius of curvature is invariable and equal to  $r$ .

If we proceed to another differentiation, we find

$$\left\{1 + \left(\frac{dy}{dx}\right)^2\right\} \frac{d^3y}{dx^3} - 3 \frac{dy}{dx} \left(\frac{d^2y}{dx^2}\right)^2 = 0 \dots\dots\dots(7),$$

which is the general differential equation of a circle free from arbitrary constants. And the geometrical property which this equation also expresses is the invariability of the radius of curvature, but the expression is of a more absolute character than that of the previous equation (6). For in that equation we may attribute to  $r$  a definite value, and then it ceases to be the differential equation of all circles, and pertains to that particular circle only whose radius is  $r$ . The equation (7) admits of no such limitation.

Monge has deduced the general differential equation of lines of the second order expressed by the algebraic equation

$$ax^2 + bxy + cy^2 + ex + fy = 1.$$

It is

$$9 \left( \frac{d^2 y}{dx^2} \right)^2 \frac{d^5 y}{dx^5} - 45 \frac{d^2 y}{dx^2} \frac{d^3 y}{dx^3} \frac{d^4 y}{dx^4} + 40 \left( \frac{d^3 y}{dx^3} \right)^2 = 0.$$

But here our powers of geometrical interpretation fail, and results such as this can scarcely be otherwise useful than as a registry of integrable forms.

From the above examples it will be evident that the higher the order of the differential equation obtained by elimination of the determining constants from the equation of a curve, the higher and more absolute is the property which that differential equation expresses.

We reserve to a future Chapter the consideration of the genesis of partial differential equations as well as of ordinary differential equations involving more than two variables.

## EXERCISES.

1. Distinguish the following differential equations according to species, order, and degree, and take account of any peculiarities dependent upon their coefficients.

$$(1) \quad \frac{dy}{dx} - x^2 y = ax^5.$$

$$(2) \quad \frac{d^2 y}{dx^2} + \frac{2}{x} \frac{dy}{dx} - a^2 y = 0.$$

$$(3) \quad y = x + x \frac{dy}{dx} + \left( \frac{dy}{dx} \right)^2.$$

$$(4) \quad x \frac{dz}{dx} - y \frac{dz}{dy} = \frac{x^2}{y}.$$

$$(5) \quad \frac{d^2 u}{dx^2} + \frac{d^2 u}{dy^2} + \frac{d^2 u}{dz^2} = 0.$$

2. Explain the term 'complete primitive,' and form the differential equations of the first order of which the following are the complete primitives,  $c$  being regarded as the arbitrary constant, viz.:

- (1)  $y = cx + \sqrt{1 + c^2}.$
- (2)  $y = (x + c) e^{ax}.$
- (3)  $y = ce^{-\tan^{-1} x} + \tan^{-1} x - 1.$
- (4)  $y = (cx + \log x + 1)^{-1}.$
- (5)  $y^2 - 2cx - c^2 = 0.$
- (6)  $y = cx + \phi(c).$

3. Form the differential equations of the second order of which the following are the complete primitives,  $c$  and  $c'$  being regarded as arbitrary constants.

- (1)  $y = c \cos mx + c' \sin mx.$
- (2)  $y = c \cos (mx + c').$
- (3)  $y = x \log \frac{c + c'x}{x}.$
- (4)  $y = c \sin nx + c' \cos nx + \frac{x \sin nx}{2m}.$

4. State the criterion by which it may be determined whether differential equations are derived from a common primitive.

5. Shew that the differential equations

$$y \frac{dy}{dx} - ax = 0, \quad y^2 \left\{ 1 - \left( \frac{dy}{dx} \right)^2 \right\} = b,$$

are not derived from a common primitive involving  $a$  and  $b$  as arbitrary constants.

6. Shew that each of the following pairs of equations, in which  $p$  stands for  $\frac{dy}{dx}$ , is derived from a common primitive, and determine the primitive:

$$(1) \quad x + \frac{p}{\sqrt{1+p^2}} = a, \quad \text{and} \quad y - \frac{1}{\sqrt{1+p^2}} = b.$$

$$(2) \quad y - xp = a(y^2 + p), \quad \text{and} \quad y - xp = b(1 + x^2p).$$

7. How many first, second, third, &c. integrals belong to the general differential equation of lines of the second order given in Art. 11, and how many of each order are independent?

8. From the equation  $(y - b)^2 = 4m(x - a)$  assumed as the primitive, deduce 1st the differential equations of the first order involving  $a$  and  $b$  as their respective arbitrary constants; 2dly the general functional expression for all differential equations of the first order derivable from the same primitive.

9. Of what primitive involving two arbitrary constants would the functional equation

$$\Phi(y - 2px, p^2x) = c$$

represent all possible differential equations of the first order?

10. How many independent differential equations of all orders are derivable from a given primitive involving  $x$ ,  $y$ , and  $n$  arbitrary constants?

## CHAPTER II.

### ON DIFFERENTIAL EQUATIONS OF THE FIRST ORDER AND DEGREE BETWEEN TWO VARIABLES.

1. THE differential equations of which we shall treat in this Chapter may be represented under the general form

$$M + N \frac{dy}{dx} = 0,$$

$M$  and  $N$  being functions of the variables  $x$  and  $y$ .

In this mode of representation  $x$  is regarded as the independent variable and  $y$  as the dependent variable.

We may, however, regard  $y$  as the independent and  $x$  as the dependent variable, on which supposition the form of the typical equation will be

$$M \frac{dx}{dy} + N = 0.$$

For as any primitive equation between  $x$  and  $y$  enables us theoretically to determine either  $y$  as a function of  $x$ , or  $x$  as a function of  $y$ , it is indifferent which of the two variables we suppose independent.

It is usual to treat this equation under the form

$$Mdx + Ndy = 0,$$

not however from any preference for the theory of infinitesimals, but for the sake of symmetry.

The order of this Chapter will be the following. As the solution of the equation, if such exist, must be in the form of a relation connecting  $x$  and  $y$ , I shall first establish a preliminary proposition expressing the condition of mutual depend-

ence of functions of two variables; I shall then inquire what kind of relation between  $x$  and  $y$  is *necessarily* implied by the existence of a differential equation of the form

$$M + N \frac{dy}{dx} = 0;$$

I shall discuss certain cases in which the equation admits readily of finite solution; and I shall lastly deduce its general solution in a series.

PROP. 1. *Let  $V$  and  $v$  be explicit functions of the two variables  $x$  and  $y$ . Then, if  $V$  be expressible as a function of  $v$ , the condition*

$$\frac{dV}{dx} \frac{dv}{dy} - \frac{dV}{dy} \frac{dv}{dx} = 0 \dots\dots\dots(1)$$

*will be identically satisfied. Conversely, if this condition be identically satisfied,  $V$  will be expressible as a function of  $v$ .*

1st. For suppose  $V = \phi(v)$ . Then

$$\frac{dV}{dx} = \frac{d\phi(v)}{dv} \frac{dv}{dx},$$

$$\frac{dV}{dy} = \frac{d\phi(v)}{dv} \frac{dv}{dy}.$$

Multiplying the first equation by  $\frac{dv}{dy}$ , the second by  $\frac{dv}{dx}$ , and subtracting, we have

$$\frac{dV}{dx} \frac{dv}{dy} - \frac{dV}{dy} \frac{dv}{dx} = 0.$$

And this is satisfied *identically*; since by the process of elimination the second member vanishes independently both of the form of  $v$  as a function of  $x$  and  $y$ , and of the form of  $V$  as a function of  $v$ .

2ndly. Also if the above condition be satisfied identically,  $V$  will be expressible as a function of  $v$ . For whatever functions  $V$  and  $v$  may be of  $x$  and  $y$ , it will be possible by elimi-

nating one of the variables  $x$  and  $y$  to express  $V$  as a function of the other variable and of  $v$ . Suppose for instance the expression for  $V$  thus obtained to be

$$V = \phi(x, v).$$

Then

$$\frac{dV}{dx} = \frac{d\phi(x, v)}{dx} + \frac{d\phi(x, v)}{dv} \frac{dv}{dx},$$

$$\frac{dV}{dy} = \frac{d\phi(x, v)}{dv} \frac{dv}{dy}.$$

Substituting these values of  $\frac{dV}{dx}$  and  $\frac{dV}{dy}$  in the equation (1) we have as the result

$$\frac{d\phi(x, v)}{dx} \frac{dv}{dy} = 0 \dots\dots\dots (2).$$

But,  $v$  being by hypothesis an explicit function of both variables  $x$  and  $y$ ,  $\frac{dv}{dy}$  is not identically 0. Hence, from (2),

$$\frac{d\phi(x, v)}{dx} = 0$$

identically. Therefore  $\phi(x, v)$ , which represents  $V$ , does not contain  $x$  in its expression; and  $V$  reduces simply to a function of  $v$ .

We have supposed each of the functions  $V$  and  $v$  to contain both the variables  $x$  and  $y$ . But, whether this be or be not the case, the identical satisfying of (1) is the necessary and sufficient condition of the functional dependence of  $V$  and  $v$ .

For suppose either  $V$  or  $v$ , and for distinction we shall choose  $v$ , to be a function of one of the variables only, as  $x$ , and  $V$  to be a function of  $v$ . Then is  $V$  also a function of  $x$ , and as  $\frac{dv}{dy}$  and  $\frac{dV}{dy}$  vanish identically the condition (1) is satisfied.

Conversely, supposing  $v$  to be a function of  $x$  only, and (1) to be identically satisfied, that equation reduces to

$$\frac{dV}{dy} = 0,$$

whence  $V$  is expressible as a function of  $v$ .

2. The equation  $M + N \frac{dy}{dx} = 0$  always involves the existence of a primitive relation between  $x$  and  $y$  of the form

$$f(x, y) = c,$$

in which  $c$  is an arbitrary constant.

Let us first consider what is the *immediate* signification of the equation

$$M + N \frac{dy}{dx} = 0 \dots\dots\dots (1).$$

We know that if  $\Delta x$  represent any finite increment of  $x$ , and  $\Delta y$  the corresponding finite increment of  $y$ ,  $\frac{dy}{dx}$  will represent the *limit* to which the ratio  $\frac{\Delta y}{\Delta x}$  approaches as  $\Delta x$  approaches to 0.

Let us then first examine the interpretation of the equation

$$M + N \frac{\Delta y}{\Delta x} = 0 \dots\dots\dots (2).$$

We have  $\frac{\Delta y}{\Delta x} = -\frac{M}{N}$ . The second member of this equation being a function of  $x$  and  $y$ , since  $M$  and  $N$  are functions of those variables, we may write

$$\frac{\Delta y}{\Delta x} = \phi(x, y) \dots\dots\dots (3),$$

the form of  $\phi(x, y)$  being known when  $M$  and  $N$  are given.

Now if we assign to  $x$  any series of values, it is possible to assign a corresponding series of values of  $y$ , any one of which being fixed arbitrarily all the others will be determined by (3).

Thus let  $x_0, x_1, x_2 \dots$  be the series of arbitrary values of  $x$ , and  $y_0$  an arbitrary value of  $y$  corresponding to  $x_0$  as the value of  $x$ , then, representing by  $\Delta x_0$  the increment of  $x_0$ , i.e. the value which being added to  $x_0$  converts it into  $x_1$ , we have by (3)

$$\Delta y_0 = \phi(x_0, y_0) \Delta x_0;$$

therefore  $y_0 + \Delta y_0 = y_0 + \phi(x_0, y_0) \Delta x_0$ .

But as  $\Delta y_0$  represents the increment of  $y_0$  corresponding to  $\Delta x_0$  as the increment of  $x_0$  it is evident that  $y_0 + \Delta y_0$  will be the value of  $y$  corresponding to  $x_0 + \Delta x_0$  as the value of  $x$ . Representing then this value of  $y$  by  $y_1$  we shall have

$$\begin{aligned} y_1 &= y_0 + \phi(x_0, y_0) \Delta x_0 \\ &= y_0 + \phi(x_0, y_0) (x_1 - x_0) \dots \dots \dots (4). \end{aligned}$$

In like manner we shall find

$$y_2 = y_1 + \phi(x_1, y_1) (x_2 - x_1) \dots \dots \dots (5),$$

but,  $y_1$  being already determined by (4),  $y_2$  is determined, and continuing the operation, a series of values of  $y$  will be determined, only one of which is arbitrary, while all the others are assigned in terms of that arbitrary value and of the known values of  $x$ .

If, for example, we have the particular equation

$$\Delta y = (x + y) \Delta x,$$

and assign to  $x$  the series of values 0, 1, 2, 3, 4, &c., and at the same time assume that when  $x$  is equal to 0,  $y$  is equal to 1, we shall have the two following corresponding series of values, viz.

$$\begin{aligned} x_0 &= 0, & x_1 &= 1, & x_2 &= 2, & x_3 &= 3, & x_4 &= 4, & \&c. \\ y_0 &= 1, & y_1 &= 2, & y_2 &= 5, & y_3 &= 12, & y_4 &= 27, & \&c. \end{aligned}$$

By assigning a different value to  $y_0$ , or by assuming arbitrarily the value of some other term of the series  $y_0, y_1, y_2, \&c.$  we should find another set of values of those quantities corresponding to the given values of  $x$ . But, in every such set,

the values of all the terms but one will be determined by a law.

Now if the intervals between the successive values of  $x$  are diminished, while the number is proportionately increased, each of the corresponding sets of values of  $x$  and  $y$  will more and more approach to the state of continuous magnitude. And, in the limit, to every conceivable value of  $x$  will correspond a value of  $y$ , determined in subjection to a continuous law—to a law however which permits us to assign one of the values of  $y$  arbitrarily. The analytical expression of that law will be the solution of the differential equation given.

3. To illustrate the same doctrine geometrically, if  $x$  and  $y$  represent rectangular co-ordinates, any system such as the above would represent a series of points of which the abscissæ having been assumed arbitrarily, the corresponding values of  $y$ , except one, are determined by a continuous law. In the limit, that series of points would approximate to a curve the *species* of which as dependent upon the form of its equation would be determined by a law, but an *element* of which, represented by a constant in that equation, would be left arbitrary, so as to permit us to draw the curve through a given point.

The form of the analytical solution thus indicated is

$$f(x, y) = c \dots \dots \dots (6).$$

The genesis of differential equations of the first order and degree from equations of this description has already been explained in Chap. I. Art. 6. It is evident that, as  $c$  is arbitrary, such a value may be assigned to it as to make a given value of  $y$  correspond to a given value of  $x$ . If those corresponding values are  $x_0, y_0$ , we have only to assume

$$f(x_0, y_0) = c \dots \dots \dots (7),$$

whence  $c$  is determined. But  $c$  being once determined, all the values of  $y$  depend upon those of  $x$ , in obedience to the law expressed by (6).

Lastly it may be shewn that two distinct complete primitives of  $Mdx + Ndy = 0$  cannot exist.

For suppose that there are two such primitives

$$u = c, \quad v = c';$$

then by differentiating each

$$\frac{du}{dx} + \frac{du}{dy} \frac{dy}{dx} = 0, \quad \frac{dv}{dx} + \frac{dv}{dy} \frac{dy}{dx} = 0;$$

whence, eliminating  $\frac{dy}{dx}$ ,

$$\frac{du}{dx} \frac{dv}{dy} - \frac{du}{dy} \frac{dv}{dx} = 0,$$

which shews, by Prop. 1, that  $v$  is a function of  $u$ . The second equation is then equivalent to

$$f(u) = c',$$

and this is resolvable by solution into equations of the form

$$u = c,$$

each of which is therefore only a repetition of the first supposed complete primitive.

*Certain cases in which the equation  $Mdx + Ndy = 0$  admits of finite solution.*

4. The equation  $Mdx + Ndy = 0$  can always be solved when the variables in  $M$  and  $N$  admit of being separated; i.e. when the equation can be reduced to the form

$$Xdx + Ydy = 0 \dots\dots\dots(8),$$

in which  $X$  is a function of  $x$  alone, and  $Y$  a function of  $y$  alone.

To solve the equation in its reduced form (8), it is only necessary to integrate the two terms separately, and to equate the result to an arbitrary constant. Thus the solution will be

$$\int Xdx + \int Ydy = c \dots\dots\dots(9).$$

On differentiating this result the arbitrary constant  $c$  disappears, and (8) is reproduced.

Thus the solution of the equation

$$x dx + y dy = 0$$

will be

$$\frac{x^2 + y^2}{2} = c,$$

or, since  $c$  is arbitrary,

$$x^2 + y^2 = c.$$

The solution of the equation

$$\frac{dx}{1+x} + \frac{dy}{1+y} = 0$$

will in like manner be

$$\log(1+x) + \log(1+y) = c;$$

a result which may be simplified in the following manner. We have

$$\log(1+x)(1+y) = c;$$

therefore

$$(1+x)(1+y) = e^c.$$

But *a function of an arbitrary constant is itself an arbitrary constant*. Hence we may write as the solution

$$(1+x)(1+y) = C.$$

Indeed it frequently happens that solutions which present themselves in a transcendental form admit of being reduced to an algebraic form.

Thus also the solution of the equation

$$\frac{dx}{\sqrt{1-x^2}} + \frac{dy}{\sqrt{1-y^2}} = 0 \dots\dots\dots(10)$$

being

$$\sin^{-1} x + \sin^{-1} y = c,$$

we shall have, on taking the sine of both members of the equation and replacing  $\sin c$  by  $C$ ,

$$x \sqrt{1-y^2} + y \sqrt{1-x^2} = C \dots\dots\dots(11),$$

which is algebraic.

5. Different modes of integration will also give rise to solutions which at first sight appear to be discordant. The discordance however will be only apparent. Thus if we express the equation last solved in the form

$$\frac{-dx}{\sqrt{1-x^2}} + \frac{-dy}{\sqrt{1-y^2}} = 0,$$

and integrate by means of the formula

$$\int \frac{-dx}{\sqrt{1-x^2}} = \cos^{-1} x + \text{const.},$$

we shall have

$$\cos^{-1} x + \cos^{-1} y = C_1$$

and, taking the cosine of both members,

$$xy - \sqrt{(1-x^2)(1-y^2)} = \cos C_1 \dots\dots\dots(12).$$

The last result may however be reduced to the form

$$x\sqrt{1-y^2} + y\sqrt{1-x^2} = \sin C_1 \dots\dots\dots(13),$$

which, as  $\sin C_1$  is arbitrary, agrees with the previous result, (11).

The constants  $C$  and  $C_1$  are seen to be connected by a relation  $C = \sin C_1$ , which is independent of the variables  $x$  and  $y$ .

And in general the test of the accordance of two solutions of a differential equation, each involving an arbitrary constant, is, that on *eliminating one of the variables, the other variable will disappear also, and a relation between the arbitrary constants alone result.*

Or expressing the solutions in the form

$$V = C, \quad v = c,$$

we may directly apply the test of equivalence

$$\frac{dV}{dx} \frac{dv}{dy} - \frac{dV}{dy} \frac{dv}{dx} = 0,$$

resulting from the proposition in Art. 1.

6. It sometimes happens that the variables may be separated by multiplying or dividing the equation by a factor. Thus the equation

$$\frac{x dx}{1+y} - \frac{y dy}{1+x} = 0$$

becomes on multiplying by  $(1+x)(1+y)$ ,

$$x(1+x) dx - y(1+y) dy = 0,$$

in which the variables are separated. Integration then gives

$$\frac{x^2}{2} + \frac{x^3}{3} - \frac{y^2}{2} - \frac{y^3}{3} = c.$$

The most general form of equations in which the variables can be separated by the process above mentioned is

$$X_1 Y_1 dx + X_2 Y_2 dy = 0 \dots\dots\dots(14),$$

in which  $X_1$  and  $X_2$  are functions of  $x$  only, and  $Y_1$  and  $Y_2$  functions of  $y$  only. On dividing the above equation by  $Y_1 X_2$ , or, which amounts to the same thing, multiplying it by the factor  $\frac{1}{Y_1 X_2}$ , we have

$$\frac{X_1}{X_2} dx + \frac{Y_2}{Y_1} dy = 0 \dots\dots\dots(15),$$

in which the variables are separated.

Ex. The equation  $x \sqrt{1+y^2} dx + y \sqrt{1+x^2} dy = 0$  is thus reduced to

$$\frac{x dx}{\sqrt{1+x^2}} + \frac{y dy}{\sqrt{1+y^2}} = 0,$$

and has for its complete integral

$$\sqrt{1+x^2} + \sqrt{1+y^2} = c.$$

7. Sometimes too the variables in the equation

$$M dx + N dy = 0$$

admit of being separated after a preliminary transformation.

Ex. 1. If in the equation  $(x - y^2) dx + 2xydy = 0$ , we assume  $y = \sqrt{xz}$ , we find

$$dy = \frac{zdx + xdz}{2\sqrt{xz}}.$$

Substituting these expressions for  $y$  and  $dy$  in the given equation, we have

$$\frac{dx}{x} + dz = 0.$$

Therefore integrating and replacing  $z$  by its value  $\frac{y^2}{x}$ ,

$$\log x + \frac{y^2}{x} = c.$$

Ex. 2.  $(y - x)(1 + x^2)^{\frac{1}{2}} dy - n(1 + y^2)^{\frac{3}{2}} dx = 0.$

Assume  $x = \tan \theta$ ,  $y = \tan \phi$ . We find

$(\tan \phi - \tan \theta) \sec \theta \sec^2 \phi d\phi - n \sec^3 \phi \sec^2 \theta d\theta = 0,$   
which reduces to

$$\sin(\phi - \theta) d\phi - nd\theta = 0.$$

Now let  $\phi - \theta = \psi$ , then

$$\sin \psi d\phi = nd\phi - nd\psi,$$

therefore  $d\phi = \frac{nd\psi}{n - \sin \psi};$

whence  $\phi = \int \frac{nd\psi}{n - \sin \psi} + c:$

the integral in the second member is a known form.

It will be remarked that the transformations employed in the above examples are not very obvious ones. They would scarcely be suggested by the forms of the differential equations themselves. And in the present state of analysis, it would be impossible to lay down any general direction on the subject. There are however certain classes of differential equations in which the nature of the required transformation can be determined. Among them a foremost place is due to homogeneous equations.

*Homogeneous Equations.*

8. The differential equation  $Mdx + Ndy = 0$  is said to be homogeneous when  $M$  and  $N$  are homogeneous functions of  $x$  and  $y$ , and are of the same degree.

Thus the equation

$$\{y + \sqrt{(x^2 + y^2)}\} dx - xdy = 0$$

is a homogeneous equation,  $M$  and  $N$  being here of the first degree.

To integrate a homogeneous equation it suffices to assume  $y = vx$ . In the transformed equation the variables  $x$  and  $v$  will then admit of separation.

Thus in the above example we should find

$$\{vx + x\sqrt{(1 + v^2)}\} dx - x(vdx + xdv) = 0,$$

whence dividing by  $x$

$$\sqrt{(1 + v^2)} dx - xdv = 0,$$

from which result

$$\frac{dx}{x} - \frac{dv}{\sqrt{(1 + v^2)}} = 0;$$

$$\log x - \log \{v + \sqrt{(1 + v^2)}\} = c.$$

Replacing  $v$  by  $\frac{y}{x}$ , we have

$$\log x - \log \left\{ \frac{y + \sqrt{(x^2 + y^2)}}{x} \right\} = c,$$

for the complete primitive.

As in Art. 5, the above solution admits of a simpler expression. Freed from transcendents and radicals, it gives

$$x^2 = 2Cy + C^2,$$

$C$  being an arbitrary constant.

To demonstrate the above method generally, let us suppose that  $M$  and  $N$  are homogeneous functions of  $x$  and  $y$  of the

$n^{\text{th}}$  degree. We may then, in accordance with the known type of homogeneous functions, write

$$M = x^n \phi \left( \frac{y}{x} \right), \quad N = x^n \psi \left( \frac{y}{x} \right),$$

so that the equation  $Mdx + Ndy = 0$  becomes on substitution and division by the common factor  $x^n$ ,

$$\phi \left( \frac{y}{x} \right) dx + \psi \left( \frac{y}{x} \right) dy = 0 \dots \dots \dots (16).$$

Now assuming  $y = vx$ , we have

$$\frac{y}{x} = v, \quad dy = vdx + xdv,$$

and the above equation becomes

$$\phi(v) dx + \psi(v) (vdx + xdv) = 0.$$

$$\text{Or,} \quad \{\phi(v) + v\psi(v)\} dx + \psi(v) xdv = 0.$$

Therefore

$$\frac{dx}{x} + \frac{\psi(v) dv}{\phi(v) + v\psi(v)} = 0 \dots \dots \dots (17),$$

whence on integrating

$$\log x + \int \frac{\psi(v) dv}{\phi(v) + v\psi(v)} = C \dots \dots \dots (18).$$

It is obvious from the symmetry of the relation between  $x$  and  $y$  that we might equally employ the transformation  $\frac{x}{y} = v$  and regard  $v$  and  $y$  as the new variables. What is essential in the method is the substitution, in place of the original variables  $x$  and  $y$ , of a new system of variables, consisting of one variable of the old system, and of the ratio which is borne to it by the other variable of that system.

Ex. It is required to integrate the equation

$$\{x - \sqrt{(xy)} - y\} dx + \sqrt{(xy)} dy = 0,$$

by the direct application of (18). Here,  $n = 1$ ,

$$M = x - \sqrt{(xy)} - y = x \{1 - \sqrt{(v)} - v\},$$

$$N = \sqrt{(xy)} = x \sqrt{(v)}.$$

Thus we have

$$\phi(v) = 1 - v^{\frac{1}{2}} - v,$$

$$\psi(v) = v^{\frac{1}{2}},$$

and (18) gives

$$\log x + \int \frac{v^{\frac{1}{2}} dv}{1 - v^{\frac{1}{2}} - v + v^{\frac{3}{2}}} = C.$$

To effect the integration in the second term, let  $v = t^2$ .

$$\begin{aligned} \text{Then } \int \frac{v^{\frac{1}{2}} dv}{1 - v^{\frac{1}{2}} - v + v^{\frac{3}{2}}} &= \int \frac{2t^2 dt}{1 - t - t^2 + t^3} \\ &= \frac{1}{1 - t} + \frac{3}{2} \log(1 - t) + \frac{1}{2} \log(1 + t) \\ &= \frac{1}{1 - t} + \log(1 - t) + \frac{1}{2} \log(1 - t^2). \end{aligned}$$

Hence finally, replacing  $t$  by  $\frac{y^{\frac{1}{2}}}{x^{\frac{1}{2}}}$ ,

$$\frac{x^{\frac{1}{2}}}{x^{\frac{1}{2}} - y^{\frac{1}{2}}} + \log(x^{\frac{1}{2}} - y^{\frac{1}{2}}) + \frac{1}{2} \log(x - y) = C.$$

9. The equation

$$(ax + by + c) dx + (a'x + b'y + c') dy = 0 \dots \dots \dots (19)$$

may be rendered homogeneous, either first by assuming

$$x = x' - \alpha, \quad y = y' - \beta,$$

and properly determining  $\alpha$  and  $\beta$ ; or secondly by assuming

$$ax + by + c = x', \quad a'x + b'y + c' = y'.$$

The first transformation gives

$$(ax' + by' - a\alpha - b\beta + c) dx' + (a'x' + b'y' - a'\alpha - b'\beta + c') dy' = 0,$$

whence if  $\alpha$  and  $\beta$  be determined by the conditions

$$a\alpha + b\beta = c,$$

$$a'\alpha + b'\beta = c',$$

we shall have the homogeneous equation

$$(ax' + by') dx' + (a'x' + b'y') dy' = 0.$$

Making then  $y' = vx'$  we find

$$\frac{dx'}{x'} + \frac{(a' + b'v) dv}{a + (b + a')v + b'v^2} = 0 \dots\dots\dots (20),$$

which is directly integrable.

The second transformation gives

$$adx + bdy = dx', \quad a'dx + b'dy = dy',$$

whence determining  $dx$  and  $dy$ , the proposed equation assumes the homogeneous form

$$(b'x' - a'y') dx' - (bx' - ay') dy' = 0.$$

Both these transformations fail if  $ab' - a'b = 0$ . But in this case, since  $b' = \frac{a'b}{a}$ , the proposed equation may be expressed in the form

$$(ax + by + c) dx + \frac{a'}{a} \left( ax + by + \frac{ac'}{a'} \right) dy = 0,$$

and the variables will be separated if we assume  $ax + by = z$ , and then adopt either  $z$  and  $x$  or  $z$  and  $y$  as the new variables.

These transformations are linear, and by one of the two the proposed equation is usually solved.

[For another method see the *Supplementary Volume*, Chapter XIX, Arts. 1 and 2.]

10. The linear differential equation of the first order and degree

$$\frac{dy}{dx} + Py = Q \dots\dots\dots (21),$$

$P$  and  $Q$  being functions of  $x$ , admits of being solved. When  $Q = 0$  the solution is obtained by separating the variables; and when  $Q$  is not equal to 0, a solution may be founded upon that of the previous and simpler case.

It must be observed that the linear equation (21), when reduced to the form

$$(Py - Q) dx + dy = 0,$$

falls under the general type,  $Mdx + Ndy = 0$ .

1st, When  $Q = 0$ , we have

$$\frac{dy}{dx} + Py = 0.$$

Dividing by  $y$ , in order to separate the variables,

$$\frac{dy}{y} = -Pdx.$$

Therefore,  $\log y = - \int Pdx + c$ , which gives

$$\begin{aligned} y &= \epsilon^{-\int Pdx + c} \\ &= C\epsilon^{-\int Pdx} \dots\dots\dots (22), \end{aligned}$$

$C$  being an arbitrary constant substituted for  $\epsilon^c$ . It has been already observed that a function of an arbitrary constant is itself an arbitrary constant; see Art. 4.

2ndly, To solve the linear equation (21) when  $Q$  is not equal to 0, let us assign to the solution the general form (22) above obtained, but suppose  $C$  to be no longer a constant but a new variable quantity—an unknown function of  $x$ , which must be

determined in accordance with the new conditions to which the solution must be subject.

Substituting then the above expression for  $y$  in (21), and observing that, since  $C$  is now variable, we have

$$\frac{dy}{dx} = \frac{d}{dx} (C\epsilon^{-fPdx}) = \frac{dC}{dx} \epsilon^{-fPdx} - CP\epsilon^{-fPdx},$$

there results

$$\frac{dC}{dx} \epsilon^{-fPdx} = Q.$$

Hence 
$$\frac{dC}{dx} = \epsilon^{fPdx} Q.$$

Therefore 
$$C = \int \epsilon^{fPdx} Q dx + c,$$

$c$  being an arbitrary constant. Substituting this *generalized* value of  $C$  in (22), we have finally

$$y = \epsilon^{-fPdx} \left( \int \epsilon^{fPdx} Q dx + c \right) \dots\dots\dots (23),$$

the solution required.

It will be observed that if  $Q = 0$ , the above solution is reduced to the form (22) before obtained.

The method of generalizing a solution above exemplified is called the method of the *variation of parameters*, the term parameter, by an extension of its use in the conic sections, being applied to denote the arbitrary constants of the solution of a differential equation. It is only, however, in certain cases that this method is successful. It is always legitimate to endeavour to adapt a solution to wider conditions by a transformation, which, like the above, only introduces a new variable instead of an old one, or a new and adequate system of variables in the room of a former system. But it is not always that the equations thus obtained are, as in the above example, easier of solution than those of which they take the place.

Ex. 1. Given  $\frac{dy}{dx} - \frac{2y}{x+1} = (x+1)^3$ .

Here  $P = \frac{-2}{x+1}$ ,  $Q = (x+1)^3$ .

Hence  $\int P dx = -2 \log (x+1)$ ,  $e^{\int P dx} = (x+1)^{-2}$ .

$$\int e^{\int P dx} Q dx = \int (x+1) dx = \frac{(x+1)^2}{2} + c.$$

Therefore  $y = (x+1)^2 \left\{ \frac{(x+1)^2}{2} + c \right\}$ .

Ex. 2. Given  $\frac{dy}{dx} - \frac{ny}{x+1} = e^x (x+1)^n$ .

Here we find  $\int P dx = -n \log (x+1)$ ,

$$e^{\int P dx} = (x+1)^{-n},$$

$$\int e^{\int P dx} Q dx = \int e^x dx = e^x.$$

Therefore  $y = (x+1)^n (e^x + c)$ .

11. Equations of the form

$$\frac{dy}{dx} + Py = Qy^n,$$

$P$  and  $Q$  being functions of  $x$ , are reducible to a linear form. For, dividing by  $y^n$ , we have

$$y^{-n} \frac{dy}{dx} + Py^{1-n} = Q.$$

Now let  $y^{1-n} = z$ , then

$$(1-n) y^{-n} \frac{dy}{dx} = \frac{dz}{dx},$$

whence  $y^{-n} \frac{dy}{dx} = \frac{1}{1-n} \frac{dz}{dx},$

so that the equation becomes

$$\frac{1}{1-n} \frac{dz}{dx} + Pz = Q,$$

$$\text{or } \frac{dz}{dx} + (1-n) Pz = (1-n) Q,$$

which is linear.

$$\text{Ex. Given } \frac{dy}{dx} + \frac{y}{x+1} = \frac{-(x+1)^3 y^3}{2}.$$

Here, dividing by  $y^3$ , we have

$$y^{-3} \frac{dy}{dx} + \frac{y^{-2}}{x+1} = -\frac{(x+1)^3}{2},$$

and, assuming  $y^{-2} = z$ ,

$$-\frac{1}{2} \frac{dz}{dx} + \frac{z}{x+1} = -\frac{(x+1)^3}{2},$$

or

$$\frac{dz}{dx} - 2 \frac{z}{x+1} = (x+1)^3.$$

The solution of this equation, which is identical in form with that of Ex. 1, is

$$z = \frac{(x+1)^4}{2} + c(x+1)^2,$$

whence

$$y = \left\{ \frac{(x+1)^4}{2} + c(x+1)^2 \right\}^{-\frac{1}{2}}.$$

*General solution by development.*

12. In the earlier portion of this Chapter it was established, by considerations founded upon the nature and interpretation of the equation

$$Mdx + Ndy = 0,$$

that it implied the existence of a primitive equation between  $x$ ,  $y$ , and an arbitrary constant. The examples of finite solution which have been given above, illustrate this truth. But

a further and more complete illustration is afforded by the presence of an arbitrary constant in the general integral of the equation, as developed in the form of a series by Taylor's theorem. This mode of solution we now proceed to exhibit.

From the given equation we have

$$\frac{dy}{dx} = -\frac{M}{N},$$

the second member of which, being a function of  $x$  and  $y$ , may be represented by  $f_1(x, y)$ . Thus we may write

$$\frac{dy}{dx} = f_1(x, y) \dots \dots \dots (24).$$

And differentiating this equation

$$\begin{aligned} \frac{d^2y}{dx^2} &= \frac{df_1(x, y)}{dx} + \frac{df_1(x, y)}{dy} \frac{dy}{dx} \\ &= \frac{df_1(x, y)}{dx} + \frac{df_1(x, y)}{dy} f_1(x, y), \end{aligned}$$

the second member of which, being a function of  $x$  and  $y$ , may be represented by  $f_2(x, y)$ . Thus we have, as a consequence of (24),

$$\frac{d^2y}{dx^2} = f_2(x, y) \dots \dots \dots (25).$$

Repeating on this equation the above process of differentiation and substitution, we have

$$\frac{d^3y}{dx^3} = f_3(x, y) \dots \dots \dots (26),$$

wherein

$$f_3(x, y) = \frac{df_2(x, y)}{dx} + \frac{df_2(x, y)}{dy} f_1(x, y).$$

And, continuing thus to repeat the same operation, we obtain

a series of equations determining the successive differential coefficients of  $y$ , in the form

$$\frac{d^n y}{dx^n} = f_n(x, y) \dots\dots\dots (27),$$

the dependence of  $f_n(x, y)$  upon  $f_{n-1}(x, y)$ , and hence ultimately upon  $f_1(x, y)$ , being determined by the general equation

$$f_n(x, y) = \frac{df_{n-1}(x, y)}{dx} + \frac{df_{n-1}(x, y)}{dy} f_1(x, y) \dots\dots (28).$$

Hence  $M$  and  $N$  being given, the expressions for

$$\frac{dy}{dx}, \quad \frac{d^2 y}{dx^2}, \quad \dots$$

are implicitly given also.

Now  $\frac{dy}{dx}, \frac{d^2 y}{dx^2},$  &c. determine the coefficients of the several terms *after the first* in the development of  $y$  in ascending powers of  $x$ , by Taylor's theorem, or more generally in ascending powers of  $x - x_0$ , where  $x_0$  is a particular value of  $x$ . Leaving that first term arbitrary, the development is thus seen to be possible, and the result, while constituting the general integral of the given differential equation, shews that that integral involves an arbitrary constant.

Actually to obtain the development, let  $\phi(x)$  represent the general value of  $y$ , and let  $y_0$  be the particular value of  $y$  corresponding to some particular and definite value,  $x_0$ , of the variable  $x$ . Then, writing  $\phi(x)$  in the form

$$\phi(x_0 + x - x_0),$$

we have, by Taylor's theorem,

$$y = \phi(x_0) + \phi'(x_0)(x - x_0) + \phi''(x_0) \frac{(x - x_0)^2}{1 \cdot 2} + \&c. \dots (29).$$

But  $\phi(x_0)$  is what  $y$  becomes when  $x = x_0$ . Hence  $\phi(x_0) = y_0$ .

Again,  $\phi'(x_0)$  is what  $\frac{d\phi(x)}{dx}$ , i.e.  $\frac{dy}{dx}$ , becomes when  $x = x_0$ .

Hence  $\phi'(x_0) = f_1(x_0, y_0)$  by (24). In like manner  $\phi''(x_0)$  is

what  $\frac{d^2y}{dx^2}$  becomes when  $x = x_0$ , and is therefore equal to  $f_2(x_0, y_0)$ . Determining thus the successive coefficients of (29), we have finally

$$y = y_0 + f_1(x_0, y_0)(x - x_0) + f_2(x_0, y_0) \frac{(x - x_0)^2}{1 \cdot 2} + \&c. \dots (30),$$

which is the general integral.

If we assume  $x_0 = 0$ , and represent the corresponding value of  $y$  by  $c$ , we have

$$y = c + f_1(0, c)x + f_2(0, c) \frac{x^2}{1 \cdot 2} + \&c. \dots (31).$$

Should however any of the coefficients in this development become infinite we must revert to the previous form, and give to  $x_0$  such a value as will render the coefficients finite, and therefore justify the application of Taylor's theorem.

Virtually the integral (30) involves like (31) only one arbitrary constant. For in applying it we are supposed to give to  $x_0$  a *definite* value, and this being done the corresponding arbitrary value of  $y_0$  constitutes the single arbitrary constant of the solution.

[See the *Supplementary Volume*, Chapter XIX, Arts. 4 and 5.]

## EXERCISES.

1. Integrate the differential equations:

$$(1) \quad (1 + x)ydx + (1 - y)xdy = 0.$$

$$(2) \quad (y^2 + xy^2)dx + (x^2 - yx^2)dy = 0.$$

$$(3) \quad xy(1 + x^2)dy - (1 + y^2)dx = 0.$$

$$(4) \quad (1 + y^2)dx - \{y + \sqrt{1 + y^2}\}(1 + x^2)^{\frac{3}{2}}dy = 0.$$

$$(5) \quad \sin x \cos y dx - \cos x \sin y dy = 0.$$

$$(6) \quad \sec^2 x \tan y dx + \sec^2 y \tan x dy = 0.$$

2. Different processes of solution present the primitive of a differential equation under the following different forms, viz.

$$\begin{aligned}\tan^{-1}(x+y) + \tan^{-1}(x-y) &= c, \\ y^2 - x^2 + 1 &= 2Cx.\end{aligned}$$

Are these results accordant?

3. Integrate the homogeneous equations :

- (1)  $(y-x) dy + y dx = 0.$
- (2)  $\{2\sqrt{xy} - x\} dy + y dx = 0.$
- (3)  $x dy - y dx - \sqrt{x^2 + y^2} dx = 0.$
- (4)  $\left(x - y \cos \frac{y}{x}\right) dx + x \cos \frac{y}{x} dy = 0.$
- (5)  $(8y + 10x) dx + (5y + 7x) dy = 0.$

4. Integrate the equations :

- (1)  $(2x - y + 1) dx + (2y - x - 1) dy = 0.$
- (2)  $(3y - 7x + 7) dx + (7y - 3x + 3) dy = 0;$

the former as an exact differential equation, the latter by reduction to a homogeneous form.

5. Explain what is meant by variation of parameters, and, having integrated the equation  $x \frac{dy}{dx} - ay = 0$ , deduce by that method the solution of the equation  $x \frac{dy}{dx} - ay = x + 1$ .

6. Integrate, by the direct application of (23), the linear equations,

- (1)  $\frac{dy}{dx} + \frac{x}{1+x^2} y = \frac{1}{2x(1+x^2)}.$
- (2)  $x(1-x^2) \frac{dy}{dx} + (2x^2-1)y = ax^3.$
- (3)  $\frac{dy}{dx} + \frac{y}{(1-x^2)^{\frac{3}{2}}} = \frac{x + \sqrt{1-x^2}}{(1-x^2)^2}.$

$$(4) \quad \frac{dy}{dx} + y \cos x = \frac{\sin 2x}{2}.$$

$$(5) \quad (1 + x^2) \frac{dy}{dx} + y = \tan^{-1} x.$$

7. Shew that the solution of the general linear equation  $\frac{dy}{dx} + Py = Q$  may be expressed in the form

$$y = \frac{Q}{P} - e^{-\int P dx} \left( C + \int e^{\int P dx} d \frac{Q}{P} \right).$$

8. Shew that,  $\phi(x)$  being any function of  $x$ , the solution of the linear equation

$$\frac{dy}{dx} - y\phi'(x) = \phi(x) \phi'(x),$$

will be  $y = ce^{\phi(x)} - \phi(x) - 1$ .

9. Shew that if in the linear equation  $\frac{dy}{dx} + Py = Q$  we represent  $\frac{dy}{dx}$  by  $p$ , and then, differentiating and eliminating  $y$ , form a differential equation between  $p$  and  $x$ , that equation will also be linear.

10. Integrate the differential equations :

$$(1) \quad (1 - x^2) \frac{dz}{dx} - xz = axz^2.$$

$$(2) \quad 3z^2 \frac{dz}{dx} - az^3 = x + 1.$$

$$(3) \quad \frac{dz}{dx} + 2xz = 2ax^3z^3.$$

$$(4) \quad \frac{dz}{dx} + z \cos x = z^n \sin 2x.$$

$$(5) \quad x \frac{dy}{dx} + y = y^2 \log x.$$

## CHAPTER III.

### EXACT DIFFERENTIAL EQUATIONS OF THE FIRST DEGREE.

1. As the cases considered in the previous Chapter under which the equation  $Mdx + Ndy = 0$  is integrable by the separation of the variables, are but a small number of the cases in which a solution expressible in finite terms exists, Analysts have engaged in a more fundamental inquiry of which the following are the objects, viz.

1st, To ascertain under what conditions the equation

$$Mdx + Ndy = 0$$

is derived by immediate differentiation from a primitive of the form  $f(x, y) = c$ , and how, when those conditions are satisfied, the primitive may be found.

2ndly, To ascertain whether, when those conditions are not satisfied, it is possible to discover a factor by which the equation  $Mdx + Ndy = 0$  being multiplied, its first member will become an exact differential.

These inquiries will form the subject of this and the following Chapter.

**PROP. I.** *The one necessary and sufficient condition under which the first member of the equation  $Mdx + Ndy = 0$  is an exact differential is*

$$\frac{dM}{dy} = \frac{dN}{dx} \dots\dots\dots(1).$$

Let it be considered in the first place what is meant by the supposition that  $Mdx + Ndy$  is an exact differential. It is that  $M$  and  $N$  are partial differential coefficients with respect

to  $x$  and  $y$ ,—that there exists some function  $V$ , such that

$$\frac{dV}{dx} = M \dots \dots \dots (2),$$

$$\frac{dV}{dy} = N \dots \dots \dots (3).$$

Any relation between  $M$  and  $N$  which we can derive independently of the form of  $V$  from the above equations will be a *necessary* condition of  $Mdx + Ndy$  being an exact differential. And conversely, any relation between  $M$  and  $N$  which suffices to enable us to discover a function  $V$  actually satisfying the above equations (2), (3), will be a *sufficient* condition of  $Mdx + Ndy$  being an exact differential. And if the same condition should present itself in both cases, it will be both *necessary and sufficient*.

Differentiating (2) with respect to  $y$ , and (3) with respect to  $x$ , we have

$$\frac{d^2V}{dydx} = \frac{dM}{dy}, \quad \frac{d^2V}{dxdy} = \frac{dN}{dx} \dots \dots \dots (4).$$

But the first members of these equations being, by a known theorem of the Differential Calculus, equal, we have

$$\frac{dM}{dy} = \frac{dN}{dx} \dots \dots \dots (5).$$

This, therefore, is a *necessary* condition of  $Mdx + Ndy$  being an exact differential. It is also, as will next be shewn, a *sufficient* condition.

In the first place the function  $V$ , if such exist, must satisfy the equation (2).

Integrating this equation relatively to  $x$  alone (since the differentiation in  $\frac{dV}{dx}$  is relative to  $x$  alone), we have

$$V = \int Mdx + C \dots \dots \dots (6),$$

$C$  being a quantity which is constant relatively to  $x$ , so that  $\frac{dC}{dx} = 0$ . Hence, though  $C$  does not vary with  $x$ , it may vary with  $y$ , and there is nothing to limit the manner of its variation. It is therefore an *arbitrary* function of  $y$ , and we may write

$$V = \int M dx + \phi(y) \dots\dots\dots (7).$$

This is the most general form of  $V$  as a function of  $x$  and  $y$ , which satisfies the equation (2).

In the second place  $V$  must satisfy the equation (3). Substituting in that equation the value of  $V$  given in (7), we have

$$\frac{d \int M dx}{dy} + \frac{d\phi(y)}{dy} = N.$$

Therefore 
$$\frac{d\phi(y)}{dy} = N - \frac{d \int M dx}{dy}.$$

Whence 
$$\phi(y) = \int \left( N - \frac{d \int M dx}{dy} \right) dy + C \dots\dots\dots (8),$$

$C$  being simply an arbitrary constant, since, as the constant of integration with respect to  $y$  it cannot contain  $y$ , and as part of the expression for  $\phi(y)$  it cannot contain  $x$ .

Now the integration in the second member is theoretically possible (though its expression in finite terms may not be possible) if the coefficient of  $dy$ , viz.  $N - \frac{d \int M dx}{dy}$ , is a function of  $y$  only, i.e. if its differential coefficient with respect to  $x$  is 0. Expressing this condition, we have

$$\frac{dN}{dx} - \frac{d}{dx} \frac{d \int M dx}{dy} = 0 \dots\dots\dots (9).$$

But 
$$\begin{aligned} \frac{d}{dx} \frac{d \int M dx}{dy} &= \frac{d}{dy} \frac{d \int M dx}{dx} \\ &= \frac{dM}{dy}. \end{aligned}$$

Thus the condition (9) becomes

$$\frac{dN}{dx} - \frac{dM}{dy} = 0 \dots\dots\dots(10).$$

This then is a *sufficient*, as it has before been shewn to be a *necessary* condition of  $Mdx + Ndy$  being an exact differential.

The substitution in (7) of the value of  $\phi(y)$  found in (8) gives

$$V = \int Mdx + \int \left( N - \frac{d}{dy} \int Mdx \right) dy + C \dots\dots(11).$$

Finally, supposing still the condition (10) satisfied, the solution of the equation  $Mdx + Ndy = 0$  will be

$$\int Mdx + \int \left( N - \frac{d}{dy} \int Mdx \right) dy = C \dots\dots\dots(12).$$

2. The practical rule to which the above investigation leads is the following.

To solve the equation  $Mdx + Ndy = 0$  when its first member is an exact differential, integrate  $Mdx$  with respect to  $x$ , regarding  $y$  as constant, and adding, instead of an arbitrary constant, an arbitrary function of  $y$ , which must afterwards be determined by the condition that the differential coefficient of the sum with respect to  $y$  shall be equal to  $N$ . Then that sum equated to an arbitrary constant will be the solution required.

Ex. 1. Given  $(x^2 - 4xy - 2y^2) dx + (y^2 - 4xy - 2x^2) dy = 0$ .

Here  $M = x^2 - 4xy - 2y^2$  and  $N = y^2 - 4xy - 2x^2$ , whence

$$\frac{dM}{dy} = \frac{dN}{dx} = -4x - 4y,$$

and the first member of the given equation is an exact differential.

Now 
$$\int M dx = \frac{x^3}{3} - 2x^2y - 2y^2x + \phi(y) \dots\dots\dots (1),$$

the arbitrary function  $\phi(y)$  occupying, according to the rule, the place of the constant of integration. To determine  $\phi(y)$ , we have

$$\frac{d}{dy} \left\{ \frac{x^3}{3} - 2x^2y - 2y^2x + \phi(y) \right\} = y^2 - 4xy - 2x^2.$$

Whence 
$$\frac{d\phi(y)}{dy} = y^2,$$

$$\phi(y) = \frac{y^3}{3}.$$

Substituting this value in the second member of (1), and equating the result to an arbitrary constant, we have

$$\frac{x^3}{3} - 2x^2y - 2y^2x + \frac{y^3}{3} = C,$$

the solution required.

Ex. 2. Given 
$$\frac{dx}{\sqrt{(x^2 + y^2)}} + \left\{ 1 - \frac{x}{\sqrt{(x^2 + y^2)}} \right\} \frac{dy}{y} = 0.$$

Here 
$$M = \frac{1}{\sqrt{(x^2 + y^2)}}, \quad N = \frac{1}{y} - \frac{x}{y\sqrt{(x^2 + y^2)}}.$$

Hence we find

$$\frac{dM}{dy} = \frac{-y}{(x^2 + y^2)^{\frac{3}{2}}} = \frac{dN}{dx}.$$

To obtain the complete integral we will on this occasion employ directly the general form of solution (12). We have

$$\int M dx = \log \{x + \sqrt{(x^2 + y^2)}\},$$

$$\frac{d}{dy} \int M dx = \frac{1}{y} - \frac{x}{y\sqrt{(x^2 + y^2)}}.$$

Hence 
$$N - \frac{d}{dy} \int M dx = 0,$$
 so that (12) gives simply

$$\log \{x + \sqrt{(x^2 + y^2)}\} = c.$$

Substituting  $\log C$  for  $c$ , and then freeing the equation from logarithmic signs and from radicals, we have

$$y^2 = C^2 - 2Cx.$$

3. We may in many cases either dispense with the application of the criterion (1), or greatly simplify its application, by attending to the two following principles, viz.

1st, If  $Mdx + Ndy$  can be divided into two portions, one of which is manifestly an exact differential, it suffices to ascertain whether the other is such.

2ndly, If  $Mdx + Ndy$ , or that portion of it which, according to the above principle, it may suffice to examine, can be resolved into two factors, one of which is manifestly the exact differential of a function of  $x$  and  $y$ , which we will represent by  $u$ , then when the other factor is expressible as a function of  $u$ , we shall have an expression of the form  $f(u) du$  which is necessarily an exact differential.

Ex. Given  $\left\{x + \frac{1}{\sqrt{(y^2 - x^2)}}\right\} dx + \left\{y - \frac{x}{y\sqrt{(y^2 - x^2)}}\right\} dy = 0.$

This equation may be expressed in the form

$$x dx + y dy + \frac{y dx - x dy}{y\sqrt{(y^2 - x^2)}} = 0.$$

Now,  $x dx + y dy$  being an exact differential, it suffices to examine whether the term  $\frac{y dx - x dy}{y\sqrt{(y^2 - x^2)}}$  is such also.

This term may be expressed in the form of the product

$$\frac{y}{\sqrt{(y^2 - x^2)}} \times \frac{y dx - x dy}{y^2},$$

the second factor of which is the differential of  $\frac{x}{y}$ . If we make  $\frac{x}{y} = u$  the product assumes the form  $\frac{du}{\sqrt{(1 - u^2)}}$ , which is the differential of  $\sin^{-1} u$ .

The complete primitive is therefore

$$\frac{x^2 + y^2}{2} + \sin^{-1} \frac{x}{y} = c.$$

4. The converse form of the property last noticed is of sufficient importance to be stated as a distinct proposition, namely,

Prop. II. If  $U$  and  $u$  be functions of  $x$  and  $y$ , and  $Udu$  be an exact differential, then  $U$  will be a function of  $u$ .

For 
$$Udu = U \frac{du}{dx} dx + U \frac{du}{dy} dy.$$

Hence the second member being an exact differential we have by Prop. I.

$$\frac{d}{dy} \left( U \frac{du}{dx} \right) - \frac{d}{dx} \left( U \frac{du}{dy} \right) = 0,$$

therefore 
$$\frac{dU}{dy} \frac{du}{dx} - \frac{dU}{dx} \frac{du}{dy} = 0.$$

Therefore, by the proposition in the first Article of the second Chapter,  $U$  will be a function of  $u$ .

### EXERCISES.

1.  $(x^3 + 3xy^2) dx + (y^3 + 3x^2y) dy = 0.$

2.  $\left(1 + \frac{y^2}{x^2}\right) dx - 2 \frac{y}{x} dy = 0.$

3.  $\frac{2x dx}{y^3} + \left(\frac{1}{y^2} - \frac{3x^2}{y^4}\right) dy = 0.$

4.  $x dx + y dy + \frac{xdy - ydx}{x^2 + y^2} = 0.$

5.  $(1 + \epsilon^{\frac{x}{y}}) dx + \epsilon^{\frac{x}{y}} \left(1 - \frac{x}{y}\right) dy = 0.$

6.  $\epsilon^x (x^2 + y^2 + 2x) dx + 2y\epsilon^x dy = 0.$

$$7. \quad \{n \cos (nx + my) - m \sin (mx + ny)\} dx \\ + \{m \cos (nx + my) - n \sin (mx + ny)\} dy = 0.$$

8. Shew, without applying the criterion, that the following are exact differentials, viz.

$$\text{1st,} \quad \frac{x dx + y dy}{(1 + x^2 + y^2)^{\frac{1}{2}}} + \frac{y dx - x dy}{x^2 + y^2} = 0.$$

$$\text{2ndly,} \quad \frac{x dx + y dy}{(x^2 + y^2)^{\frac{1}{2}} (1 - x^2 - y^2)^{\frac{1}{2}}} + \left\{ \frac{1}{y \sqrt{(y^2 - x^2)}} + \frac{e^{\frac{x}{y}}}{y^2} \right\} (y dx - x dy).$$

9. Integrate the above equations.

10. Integrate the equation  $\frac{x^a dy - a y x^{a-1} dx}{b y^2 - c x^{2a}} + x^{a-1} dx = 0$ , distinguishing between the different cases which present themselves according, 1st, as  $b$  and  $c$  are of the same or of opposite signs; 2ndly, as  $a$  is equal to, or not equal to, 0.

11. Shew by the criterion that the expression

$$\frac{\phi\left(\frac{x}{y}\right) dx + \psi\left(\frac{x}{y}\right) dy}{x \phi\left(\frac{x}{y}\right) + y \psi\left(\frac{x}{y}\right)}$$

is generally an exact differential, and exhibit the functional forms which  $\frac{dM}{dy}$  and  $\frac{dN}{dx}$  assume.

## CHAPTER IV.

### ON THE INTEGRATING FACTORS OF THE DIFFERENTIAL EQUATION $Mdx + Ndy = 0$ .

1. THE first member of the equation  $Mdx + Ndy = 0$  not being necessarily an exact differential, analysts have sought to render it such by multiplying the equation by a properly determined factor.

Thus the first member of the equation

$$(1 + y^2) dx + xy dy = 0$$

is not an exact differential, since it does not satisfy the condition  $\frac{dM}{dy} = \frac{dN}{dx}$ , but it becomes an exact differential if the equation be multiplied by  $2x$ , and its integration, which then becomes possible, leads to the primitive equation

$$x^2(1 + y^2) = c.$$

The multiplier  $2x$  is termed an integrating factor.

We propose in this Chapter to demonstrate that integrating factors of the equation  $Mdx + Ndy = 0$  always exist, to investigate some of their properties and relations, and to shew how in certain cases integrating factors may be discovered. To complete this subject we shall, in the next following Chapter, investigate a partial differential equation, upon the solution of which their general determination depends, and shall examine some of the conditions under which the solution of that equation is possible.

2. To every differential equation of the form

$$Mdx + Ndy = 0,$$

pertains an infinite number of integrating factors, all of which are included under a single functional expression.

It has been shewn, Chap. II. Art. 2, that the above equation always involves the existence of a complete primitive of the form

$$\psi(x, y) = c \dots\dots\dots(1).$$

Differentiating the last equation, we have

$$\frac{d\psi(x, y)}{dx} + \frac{d\psi(x, y)}{dy} \frac{dy}{dx} = 0 \dots\dots\dots(2).$$

The value of  $\frac{dy}{dx}$  determined as a function of  $x$  and  $y$  from this equation must be the same as the value of  $\frac{dy}{dx}$  furnished by the given differential equation expressed in the form

$$M + N \frac{dy}{dx} = 0.$$

Hence eliminating  $\frac{dy}{dx}$  between these equations we have

$$\frac{\frac{d\psi(x, y)}{dx}}{M} = \frac{\frac{d\psi(x, y)}{dy}}{N} \dots\dots\dots(3).$$

Let  $\mu$  be the value of each of these ratios, then

$$\frac{d\psi(x, y)}{dx} = \mu M, \quad \frac{d\psi(x, y)}{dy} = \mu N.$$

As  $\mu M$  and  $\mu N$  are therefore the partial differential coefficients with respect to  $x$  and  $y$  of the same function  $\psi(x, y)$ , the expression  $\mu Mdx + \mu Ndy$  will be an exact differential. Thus  $Mdx + Ndy$  is always susceptible of being made an exact differential by a factor  $\mu$ .

3. The form of the complete primitive is however without gain or loss of generality susceptible of variation. Thus the primitive  $x^2(1 + y^2) = c$ , Art. 1, might, without becoming more or less general, be presented in the forms

$$\sin \{x^2(1 + y^2)\} = c_1, \quad \log \{x^2(1 + y^2)\} = c_2,$$

or in the functional form  $f\{x^2(1 + y^2)\} = c$ , where  $c, c_1, c_2$  are arbitrary constants. And generally a complete primitive expressed in the form  $V = c$  may be expressed also in the form  $f(V) = c$ ,  $f(V)$  denoting any function of  $V$ . These variations in the form of the complete primitive imply corresponding variations in the form of the integrating factor, a special determination of which has already been given, Art. 1.

To investigate the general form under which all such special determinations are included, let us suppose  $\mu$  to be a particular integrating factor of  $Mdx + Ndy$ , and let  $\mu Mdx + \mu Ndy$  be the exact differential of a function  $\psi(x, y)$ . Then representing for the present  $\psi(x, y)$  by  $v$ , we have

$$\mu Mdx + \mu Ndy = dv.$$

Multiply this equation by  $f(v)$ , an arbitrary function of  $v$ ; such being, by Art. 4, Chap. III., the general form of a factor which will render the second member an exact differential. We have

$$\mu f(v) (Mdx + Ndy) = f(v) dv.$$

Now the second member of this equation being an exact differential the first is so also. As moreover the first member of the above equation can only become an exact differential simultaneously with the second, the factor  $\mu f(v)$  is the general form of a factor which renders  $Mdx + Ndy$  an exact differential.

We may express the above result in the following theorem.

*If  $\mu$  be an integrating factor of the equation  $Mdx + Ndy = 0$ , and if  $v = c$  be the complete primitive obtained by multiplying the equation by that factor and integrating, then  $\mu f(v)$  will be the typical form of all the integrating factors of the equation.*

Furthermore,  $f(v)$  being an arbitrary function of  $v$ , the number of such factors is infinite.

Ex. The equation

$$(x^3y - 2y^4) dx + (y^3x - 2x^4) dy = 0,$$

becomes integrable on multiplying it by the factor  $\left(\frac{1}{xy}\right)^3$ , the actual solution thus obtained being

$$\frac{x}{y^2} + \frac{y}{x^2} = c.$$

Hence the general form of the integrating factor of the equation is

$$\frac{1}{x^3y^3} f\left(\frac{x}{y^2} + \frac{y}{x^2}\right).$$

4. From the typical form of the integrating factor of the equation  $Mdx + Ndy = 0$ , it follows that if we know two particular integrating factors of the equation, the solution may be inferred without integration.

For  $\mu$  being one of the factors given, the other must be of the form  $\mu f(v)$ . If we determine their ratio by division and equate the result to an arbitrary constant we shall have

$$f(v) = c,$$

which, from what has been said in the preceding Article, is a form of the complete primitive.

5. It has been observed, Art. 1, that the discovery of an integrating factor of the differential equation  $Mdx + Ndy = 0$  generally depends on the solution of another differential equation, but there are some cases in which it presents itself on inspection. The equation

$$(xy^2 + y) dx - xdy = 0,$$

becomes integrable on being multiplied by the factor  $\frac{1}{y^2}$ , and this factor is at once suggested if we place the equation in the form

$$y^2x dx + y dx - xdy = 0.$$

We could thus, also by inspection, assign the integrating factors of any equation of the form

$$y^2 dx + \phi(x)(y dx - x dy) = 0,$$

and many other forms will readily suggest themselves. The following analysis will however lead to results of greater generality and importance.

*Special Determinations of Integrating Factors.*

6. Whatever may be the constitution of the functions  $M$  and  $N$  we have identically

$$Mdx + Ndy = \frac{1}{2} \left\{ (Mx + Ny) \left( \frac{dx}{x} + \frac{dy}{y} \right) + (Mx - Ny) \left( \frac{dx}{x} - \frac{dy}{y} \right) \right\}.$$

But  $\frac{dx}{x} + \frac{dy}{y} = d \log(xy), \quad \frac{dx}{x} - \frac{dy}{y} = d \log \left( \frac{x}{y} \right).$

Hence,

$$Mdx + Ndy = \frac{1}{2} \left\{ (Mx + Ny) d \log xy + (Mx - Ny) d \log \frac{x}{y} \right\} \quad (1).$$

The functions  $Mx + Ny$  and  $Mx - Ny$  appear in the second member of this equation as the coefficients of exact differentials. And upon the nature and relations of these functions the inquiry will now depend.

Whatever may be the constitution of  $M$  and  $N$  some one, and only one, of the following cases will present itself. Either the functions  $Mx + Ny$  and  $Mx - Ny$  will be *both* identically equal to 0, or *one* of them will be so and not the other, or *neither* of them will be identically equal to 0. These cases we will separately consider.

1st. The case of  $Mx + Ny$  and  $Mx - Ny$  being both identically equal to 0 may be dismissed, as it would involve the supposition that  $M$  and  $N$  are each identically equal to 0.

2ndly. Suppose that one of the functions  $Mx + Ny$  and  $Mx - Ny$  is identically equal to 0 and not the other, and first let  $Mx + Ny$  be identically equal to 0, then (1) becomes

$$Mdx + Ndy = \frac{1}{2}(Mx - Ny) d \log \frac{x}{y};$$

whence dividing by  $Mx - Ny$ ,

$$\frac{Mdx + Ndy}{Mx - Ny} = \frac{1}{2} d \log \frac{x}{y} \dots\dots\dots(2).$$

Now the second member being an exact differential the first member is also one. In this case then  $Mdx + Ndy$  is made an exact differential by the factor  $\frac{1}{Mx - Ny}$ . By parallel reasoning it follows that if  $Mx - Ny$  is identically equal to 0 and not  $Mx + Ny$ , an integrating factor of  $Mdx + Ndy$  will be  $\frac{1}{Mx + Ny}$ .

And thus we are led to the following theorem.

**THEOREM.** *If one only of the functions  $Mx + Ny$  and  $Mx - Ny$  is identically equal to 0, the reciprocal of the other function will be an integrating factor of the equation*

$$Mdx + Ndy = 0.$$

3rdly. Let neither of the functions  $Mx + Ny$  and  $Mx - Ny$  be identically equal to 0. Then first dividing the fundamental equation (1) by  $Mx + Ny$ , we have

$$\frac{Mdx + Ndy}{Mx + Ny} = \frac{1}{2} d \log xy + \frac{1}{2} \frac{Mx - Ny}{Mx + Ny} d \log \frac{x}{y} \dots(3).$$

Now, by Art. 3, Chap. III., the second member of the above equation becomes an exact differential (its first term being already such) if  $\frac{Mx - Ny}{Mx + Ny}$  is a function of  $\log \frac{x}{y}$ ; therefore if it is a function of  $\frac{x}{y}$ ; therefore if it is a homogeneous function of  $x$  and  $y$  of the degree 0, for the typical form of

such a function is  $\phi\left(\frac{x}{y}\right)$ ; therefore, finally, if  $M$  and  $N$  are homogeneous functions of  $x$  and  $y$  of a common degree. For let  $M$  and  $N$  be homogeneous and of the  $n^{\text{th}}$  degree. Then  $Mx - Ny$  and  $Mx + Ny$  are each of the degree  $n + 1$ , and  $\frac{Mx - Ny}{Mx + Ny}$  is of the degree 0. Thus  $M$  and  $N$  being homogeneous functions of the  $n^{\text{th}}$  degree, the second member, and therefore the first member of (3), is an exact differential.

From this conclusion, combined with the previous one, we arrive at the following theorem.

**THEOREM.** *The equation  $Mdx + Ndy = 0$  when homogeneous is made integrable by the factor  $\frac{1}{Mx + Ny}$ , unless  $Mx + Ny$  is identically equal to 0, in which case  $\frac{1}{Mx - Ny}$  is an integrating factor.*

Always then the homogeneous equation  $Mdx + Ndy = 0$  is made integrable either by the factor  $\frac{1}{Mx + Ny}$ , or by the factor  $\frac{1}{Mx - Ny}$ .

In the second place, dividing the fundamental equation (1) by  $Mx - Ny$ , we have

$$\frac{Mdx + Ndy}{Mx - Ny} = \frac{1}{2} \left( \frac{Mx + Ny}{Mx - Ny} d \log xy + d \log \frac{x}{y} \right) \dots (4),$$

of which the second member, and therefore also the first member, becomes an exact differential if  $\frac{Mx + Ny}{Mx - Ny}$  is a function of  $\log xy$ ; therefore if it is a function of  $xy$ ; therefore, finally, if  $M$  and  $N$  are of the respective forms

$$M = F_1(xy) y, \quad N = F_2(xy) x;$$

since this supposition would give

$$\frac{Mx + Ny}{Mx - Ny} = \frac{F_1(xy) + F_2(xy)}{F_1(xy) - F_2(xy)},$$

of which the second member is a function of the product  $xy$ .

Hence the following theorem.

**THEOREM.** *The equation  $Mdx + Ndy = 0$  is made integrable by the factor  $\frac{1}{Mx - Ny}$ , when  $M$  and  $N$  are of the respective forms*

$$M = F_1(xy) y, \quad N = F_2(xy) x,$$

*unless  $Mx - Ny$  is identically equal to 0, in which case  $\frac{1}{Mx + Ny}$  is an integrating factor.*

Or the theorem might be thus expressed. *The equation*

$$F_1(xy) y dx + F_2(xy) x dy = 0$$

*is made integrable by the factor*

$$\frac{1}{xy \{F_1(xy) - F_2(xy)\}},$$

*unless we have identically  $F_1(xy) - F_2(xy) = 0$ , in which case*

$$\frac{1}{xy \{F_1(xy) + F_2(xy)\}}$$

*is an integrating factor.*

We may, however, remark that, in the particular case in which  $F_1(xy) - F_2(xy) = 0$ , no factor is needed, as the differential equation may then be expressed in the form

$$F_1(xy) (y dx + x dy) = 0,$$

the first member being manifestly an exact differential.

7. The results of the above investigation may be summed up as follows.

*If either of the functions  $Mx + Ny$ ,  $Mx - Ny$  is identically equal to 0, the reciprocal of the other function is an integrating*

factor of  $Mdx + Ndy = 0$ ; but if neither of these functions is equal to 0, then  $\frac{1}{Mx + Ny}$  is an integrating factor for the equation when homogeneous, and  $\frac{1}{Mx - Ny}$  an integrating factor of the equation when susceptible of expression in the form

$$F_1(xy) ydx + F_2(xy) xdy = 0.$$

Ex. 1. Given  $x^3dx + (3x^2y + 2y^3) dy = 0$ .

This is a homogeneous equation, and its integrating factor according to the rule above given will be

$$\frac{1}{x^4 + 3x^2y^2 + 2y^4}.$$

Thus we have, as an *exact* differential equation,

$$\frac{x^3dx}{x^4 + 3x^2y^2 + 2y^4} + \frac{(3x^2y + 2y^3) dy}{x^4 + 3x^2y^2 + 2y^4} = 0 \dots\dots\dots (1).$$

Referring then to Art. 2, Chap. III., we have

$$\begin{aligned} \int Mdx &= \int \frac{x^3dx}{x^4 + 3x^2y^2 + 2y^4} \\ &= \int \left( \frac{2x}{x^2 + 2y^2} - \frac{x}{x^2 + y^2} \right) dx \\ &= \log \frac{x^2 + 2y^2}{\sqrt{(x^2 + y^2)}} + \phi(y). \end{aligned}$$

Differentiating this expression with respect to  $y$ , and comparing the result with the corresponding term in (1), we find  $\frac{d\phi(y)}{dy} = 0$ , whence  $\phi(y) = \text{const.}$ , and we have

$$\log \frac{x^2 + 2y^2}{\sqrt{(x^2 + y^2)}} = c,$$

$$\text{or } x^2 + 2y^2 = C \sqrt{(x^2 + y^2)}$$

for the integral required.

Ex. 2. Given  $(y + xy^2) dx + (x - yx^2) dy = 0$ .

This equation may be expressed in the form

$$(1 + xy) y dx + (1 - xy) x dy = 0.$$

Hence its integrating factor, as given by the rule, will be

$$\begin{aligned} \frac{1}{Mx - Ny} &= \frac{1}{(1 + xy) xy - (1 - xy) xy} \\ &= \frac{1}{2x^2y^2}. \end{aligned}$$

Rejecting the constant  $\frac{1}{2}$ , we have, on multiplying the given equation by  $\frac{1}{x^2y^2}$ ,

$$\frac{1 + xy}{x^2y} dx + \frac{1 - xy}{xy^2} dy = 0.$$

Hence

$$\int M dx = \int \frac{dx}{x^2y} + \int \frac{dx}{x} = \log x - \frac{1}{xy} + \phi(y).$$

Now  $Ndy = \frac{dy}{xy^2} - \frac{dy}{y}$ . Hence the complementary function  $\phi(y)$  will be  $-\log y$ . Thus we have

$$\log x - \log y - \frac{1}{xy} = C$$

for the integral required.

Ex. 3. Given  $(x^2y^2 + xy^3) dx - (x^3y + x^2y^2) dy = 0$ .

If we treat this as a homogeneous equation regardless of the implied conditions, we find

$$\frac{1}{Mx + Ny} = \frac{1}{0}.$$

The rule however shews that when  $Mx + Ny$  is, as in the

above example, identically equal to 0,  $\frac{1}{Mx - Ny}$  represents an integrating factor, which in the above case will be

$$\frac{1}{2(x^3y^2 + x^2y^3)}.$$

The equation is thus reduced to

$$\frac{dx}{x} - \frac{dy}{y} = 0,$$

whence we find  $y = cx$  as the complete integral.

8. From the theorems of the preceding article others of greater generality may be deduced by transformation. Thus, since the equation  $F_1(xy) y dx + F_2(xy) x dy = 0$  is made integrable by the factor  $\frac{1}{xy \{F_1(xy) - F_2(xy)\}}$ , it follows that the equation

$$F_1(uv) v du + F_2(uv) u dv = 0$$

is made integrable by the factor  $\frac{1}{uv \{F_1(uv) - F_2(uv)\}}$ ,  $u$  and  $v$  being any functions of  $x$  and  $y$ . Hence expressing  $du$  in the form  $\frac{du}{dx} dx + \frac{du}{dy} dy$ , and  $dv$  in the form  $\frac{dv}{dx} dx + \frac{dv}{dy} dy$ , we see that the equation

$$\left\{ F_1(uv) v \frac{du}{dx} + F_2(uv) u \frac{dv}{dx} \right\} dx + \left\{ F_1(uv) v \frac{du}{dy} + F_2(uv) u \frac{dv}{dy} \right\} dy = 0$$

is made integrable by the factor  $\frac{1}{uv \{F_1(uv) - F_2(uv)\}}$ , whatever functions of  $x$  and  $y$  are represented by  $u$  and  $v$ . And, on giving particular forms to these functions, particular conditions of integration of the equation  $Mdx + Ndy = 0$  present themselves.

9. An integrating factor for homogeneous equations may also be found by the following method, due to Professor Stokes, who first pointed out the necessity of taking account of the

case in which  $Mx + Ny$  is identically equal to 0. (*Cambridge Mathematical Journal*, Vol. IV. p. 241. First Series.)

Suppose  $M$  and  $N$  to be homogeneous functions of  $x$  and  $y$  of the degree  $n$ . Then we may write

$$M = x^n \phi(v), \quad N = x^n \psi(v) \dots\dots\dots(1),$$

where  $v$  stands for  $\frac{y}{x}$ .

$$\text{Hence } Mdx + Ndy = x^n \phi(v) dx + x^n \psi(v) dy \dots\dots\dots(2).$$

But  $y = xv$ , therefore  $dy = xdv + vdx$ . Substituting this value of  $dy$  in the second member, we have

$$Mdx + Ndy = x^n \{ \phi(v) + v\psi(v) \} dx + x^{n+1} \psi(v) dv \dots\dots(3).$$

Two cases here present themselves.

First, the constitution of the functions  $\phi(v)$  and  $\psi(v)$  may be such that  $\phi(v) + v\psi(v)$  may be *identically* equal to 0. This will happen if  $Mx + Ny$  is identically equal to 0, since by (1)

$$Mx + Ny = x^{n+1} \{ \phi(v) + v\psi(v) \} \dots\dots\dots(4).$$

In this case the equation (3) reduces itself to

$$Mdx + Ndy = x^{n+1} \psi(v) dv,$$

$$\text{or } \frac{Mdx + Ndy}{x^{n+1}} = \psi(v) dv.$$

Now the second member being an exact differential the first is so also, and  $Mdx + Ndy$  is therefore made integrable by the factor  $\frac{1}{x^{n+1}}$ .

Secondly, the constitution of  $\phi(v)$  and  $\psi(v)$  may be such that  $\phi(v) + v\psi(v)$  is not identically equal to 0. And this happens when  $Mx + Ny$  is not identically equal to 0.

In this case dividing both members of (3) by

$$x^{n+1} \{ \phi(v) + v\psi(v) \},$$

we have

$$\frac{Mdx + Ndy}{x^{n+1} \{ \phi(v) + v\psi(v) \}} = \frac{dx}{x} + \frac{\psi(v) dv}{\phi(v) + v\psi(v)}$$

But the second member being an exact differential the first also is such. Now

$$\frac{Mdx + Ndy}{x^{n+1} \{\phi(v) + v\psi(v)\}} = \frac{Mdx + Ndy}{Mx + Ny} \text{ by (4).}$$

Here then  $Mdx + Ndy$  is made integrable by the factor

$$\frac{1}{Mx + Ny}.$$

Combining these results together, we see that the homogeneous equation  $Mdx + Ndy = 0$  is made integrable by the factor  $\frac{1}{Mx + Ny}$ , unless the constitution of  $M$  and  $N$  is such as to make that factor infinite. In the latter case  $\frac{1}{x^{n+1}}$  will be an integrating factor,  $n$  being the degree of  $M$  and  $N$ .

The form of the supplementary integrating factor as given by the above investigation is different from that before obtained. The results are however perfectly consistent.

For a more complete analysis of the problem which has for its object the discovery of the integrating factors of a homogeneous equation we must have recourse to the method of the next Chapter.

## EXERCISES.

1. Shew by the application of the theorem of Art. 1, Chap. II., that the expression  $x^2y^2 + x^2 + y^2 + 2(xy - 1)(x + y)$  is a function of  $x$  and  $y$ , only as being a function of  $xy + x + y$ .

2. A particular integrating factor of the equation

$$2xydx + (y^2 - 3x^2)dy = 0 \text{ is } y^{-4}.$$

Prove this, and deduce another integrating factor by the formula established in Art. 6 for homogeneous equations.

3. Exhibit the general form under which all the integrating factors of the above equation are comprehended.

4. Deduce in like manner the functional expression for all the integrating factors of the equation

$$\frac{dx}{x} + \frac{dy}{y} + 2\left(\frac{dx}{y} - \frac{dy}{x}\right) = 0.$$

5. Obtain integrating factors for the homogeneous equations:

$$(1) \quad xdy - ydx = \sqrt{(x^2 + y^2)} dx.$$

$$(2) \quad (8y + 10x) dx + (5y + 7x) dy = 0.$$

$$(3) \quad (x^2 + 2xy - y^2) dx + (y^2 + 2xy - x^2) dy = 0.$$

$$(4) \quad y^2 + (xy + x^2) \frac{dy}{dx} = 0.$$

$$(5) \quad \left(x \cos \frac{y}{x} + y \sin \frac{y}{x}\right) ydx + \left(x \cos \frac{y}{x} - y \sin \frac{y}{x}\right) xdy = 0.$$

Exhibit the corresponding integrals of the above equations.

6. The formula  $\frac{1}{Mx + Ny}$  fails to give an integrating factor for the homogeneous equation  $\frac{xdy - ydx}{x^2 + y^2} = 0$ . What formula ought here to be employed and to what result does it lead?

7. Determine an integrating factor of each of the equations

$$(1) \quad (x^2y^2 + xy) ydx + (x^2y^2 - 1) xdy = 0.$$

$$(2) \quad (x^3y^3 + x^2y^2 + xy + 1) ydx + (x^3y^3 - x^2y^2 - xy + 1) xdy = 0.$$

## CHAPTER V.

### ON THE GENERAL DETERMINATION OF THE INTEGRATING FACTORS OF THE EQUATION $Mdx + Ndy = 0$ .

1. PROP. It is required to form a differential equation for determining in the most general manner the integrating factors of the equation  $Mdx + Ndy = 0$ .

Let  $\mu$  be any integrating factor of the above equation, then since  $\mu Mdx + \mu Ndy$  is by hypothesis an exact differential, we have by Prop. I. Chap. III.

$$\frac{d(\mu N)}{dx} = \frac{d(\mu M)}{dy}.$$

Hence

$$N \frac{d\mu}{dx} + \mu \frac{dN}{dx} = M \frac{d\mu}{dy} + \mu \frac{dM}{dy},$$

or, by transposition,

$$N \frac{d\mu}{dx} - M \frac{d\mu}{dy} = \left( \frac{dM}{dy} - \frac{dN}{dx} \right) \mu \dots\dots\dots(1),$$

which is the equation required.

Now this equation involves the partial differential coefficients of  $\mu$  taken with respect to  $x$  and  $y$ . It is therefore a *partial* differential equation. We have not the means of solving it *generally*, and it will hereafter appear that its general solution would demand a previous general solution of the differential equation  $Mdx + Ndy = 0$ , of which  $\mu$  is the integrating factor. But there are many cases in which we can solve the equation under some restrictive condition or hypothesis, and the form of the solution obtained will always indicate when the supposed condition or hypothesis is legitimate.

The following are examples of such solutions.

2. Let  $\mu$  be a function of one of the variables only, e.g. suppose  $\mu = \phi(x)$ , then since  $\frac{d\mu}{dy} = 0$ , we have from (1)

$$N\phi'(x) = \left(\frac{dM}{dy} - \frac{dN}{dx}\right) \phi(x).$$

Therefore

$$\frac{\phi'(x)}{\phi(x)} = \frac{\frac{dM}{dy} - \frac{dN}{dx}}{N},$$

or

$$\frac{d}{dx} \log \phi(x) = \frac{\frac{dM}{dy} - \frac{dN}{dx}}{N}.$$

Now if the second member of this equation is a function of  $x$  the equation is integrable, and we have

$$\log \phi(x) = \int \frac{\frac{dM}{dy} - \frac{dN}{dx}}{N} dx.$$

Whence

$$\mu = \epsilon^{\int \frac{\frac{dM}{dy} - \frac{dN}{dx}}{N} dx} \dots\dots\dots (2).$$

We have seen that the hypothesis assumed as the basis of the above solution, viz. that the integrating factor  $\mu$  is a function of  $x$  only, is legitimate when the constitution of the functions  $M$  and  $N$  is such that the expression

$$\left(\frac{dM}{dy} - \frac{dN}{dx}\right) \div N$$

is a function of  $x$  only. In this case (2) enables us to determine the value of  $\mu$ .

In like manner the condition under which  $\mu$  is a function of  $y$  only, is

$$\frac{\frac{dN}{dx} - \frac{dM}{dy}}{M} = \text{a function of } y \text{ only} \dots\dots\dots (3),$$

and the value of  $\mu$ , on this hypothesis, is

$$\mu = e^{\int \frac{\frac{dN}{dx} - \frac{dM}{dy}}{M} dy} \dots\dots\dots (4).$$

Ex. Let us inquire whether the equation

$$(3x^2 + 6xy + 3y^2) dx + (2x^2 + 3xy) dy = 0 \dots\dots\dots (5)$$

admits of an integrating factor which is a function of  $x$  only.

Making  $M = 3x^2 + 6xy + 3y^2$ ,  $N = 2x^2 + 3xy$ , we find

$$\frac{\frac{dM}{dy} - \frac{dN}{dx}}{N} = \frac{6x + 6y - (4x + 3y)}{2x^2 + 3xy} = \frac{1}{x},$$

and this result being a function of  $x$  alone, the determination of  $\mu$  as a function of  $x$  alone is seen to be possible. From (2) we now find

$$\mu = e^{\int \frac{dx}{x}} = Cx,$$

$C$  being an arbitrary constant.

Now multiplying (5) by  $Cx$ , we have

$$C\{(3x^3 + 6x^2y + 3xy^2) dx + (2x^3 + 3x^2y) dy\} = 0.$$

The first member of this equation remains a complete differential whatever value we assign to  $C$ . If we make  $C = 1$ , and integrate, we find

$$\frac{3x^4}{4} + 2x^3y + \frac{3x^2y^2}{2} = c,$$

the integral sought.

The student may obtain also the same result by solving (5) as a homogeneous equation.

The linear differential equation of the first order

$$\frac{dy}{dx} + Py - Q = 0 \dots\dots\dots (6),$$

$P$  and  $Q$  being functions of  $x$ , may be solved by the above method.

For, reducing it to the form

$$(Py - Q) dx + dy = 0 \dots\dots\dots (7),$$

we have  $M = Py - Q$ ,  $N = 1$ , whence

$$\frac{\frac{dM}{dy} - \frac{dN}{dx}}{N} = P,$$

which being a function of  $x$  we find from (2)

$$\mu = e^{\int P dx}$$

Multiplying (7) by the factor thus determined, we have

$$e^{\int P dx} (Py - Q) dx + e^{\int P dx} dy = 0,$$

the first member of which is now the exact differential of the function

$$e^{\int P dx} y - \int e^{\int P dx} Q dx.$$

Equating this expression to an arbitrary constant  $c$ , we find

$$y = e^{-\int P dx} \left\{ c + \int e^{\int P dx} Q dx \right\} \dots\dots\dots (8),$$

which agrees with the result of Art. 10, Chap. II.

3. *Let it be required to determine the conditions under which the equation  $Mdx + Ndy = 0$ , can be made integrable by a factor  $\mu$  which is a function of the product  $xy$ .*

Representing  $xy$  by  $v$  and making  $\mu = \phi(v)$ , the partial differential equation (1) becomes

$$N\phi'(v) \frac{dv}{dx} - M\phi'(v) \frac{dv}{dy} - \left( \frac{dM}{dy} - \frac{dN}{dx} \right) \phi(v) = 0,$$

whence, since  $\frac{dv}{dx} = y$ ,  $\frac{dv}{dy} = x$ , we find

$$\frac{\phi'(v)}{\phi(v)} = \frac{\frac{dM}{dy} - \frac{dN}{dx}}{Ny - Mx} \dots\dots\dots (9).$$

Thus the condition sought is that the second member of the

above equation be reducible to a function of  $v$  alone, i.e. of  $xy$  alone. And the corresponding value of  $\mu$  is

$$\mu = e^{\int \frac{\frac{dM}{dy} - \frac{dN}{dx}}{Ny - Mx} dv} \dots\dots\dots (10).$$

One case in which the above condition is satisfied is the following, viz.

$$F_1(xy) y dx + F_2(xy) x dy = 0 \dots\dots\dots (11).$$

Making  $M = F_1(v) y$ ,  $N = F_2(v) x$ , and observing that since

$$v = xy, \quad \frac{dv}{dx} = y, \quad \frac{dv}{dy} = x, \text{ we find}$$

$$\begin{aligned} \frac{\frac{dM}{dy} - \frac{dN}{dx}}{Ny - Mx} &= \frac{F_1(v) + v F_1'(v) - F_2(v) - v F_2'(v)}{v \{F_2(v) - F_1(v)\}} \\ &= - \frac{F_1(v) - F_2(v) + v \{F_1'(v) - F_2'(v)\}}{v \{F_1(v) - F_2(v)\}} \\ &= - \frac{1}{v} - \frac{F_1'(v) - F_2'(v)}{F_1(v) - F_2(v)}, \end{aligned}$$

a function of  $v$  alone.

Multiplying by  $dv$  and integrating, we have

$$\int \frac{\frac{dM}{dy} - \frac{dN}{dx}}{Ny - Mx} dv = -\log v - \log \{F_1(v) - F_2(v)\}.$$

Hence,

$$\mu = \frac{1}{v \{F_1(v) - F_2(v)\}} = \frac{1}{xy \{F_1(xy) - F_2(xy)\}}.$$

This accords with a result of Art. 6, Chap. IV.

[The above investigation fails when the constitution of the functions  $M$  and  $N$  is such that we have *identically*

$$Ny - Mx = 0.$$

An integrating factor for this case has already been found in the preceding Chapter.]

Ex. 1. Thus the equation  $(x^2y^2+1)ydx + (x^2y^2-1)xdy = 0$  becomes integrable on being multiplied by the factor  $\frac{1}{2xy}$ , which is found by substituting in the previous expression  $x^2y^2+1$  for  $F_1(xy)$ , and  $x^2y^2-1$  for  $F_2(xy)$ .

The final solution is

$$\frac{1}{2}x^2y^2 + \log \frac{x}{y} = c.$$

Ex. 2. The equation

$$(2x^3y^2 - y)dx + (2x^2y^3 - x)dy = 0,$$

does not fall under the type (11), but the values which it furnishes for  $M$  and  $N$  give

$$\frac{\frac{dM}{dy} - \frac{dN}{dx}}{Ny - Mx} = \frac{4x^3y - 1 - (4y^3x - 1)}{2x^2y^4 - xy - (2x^4y^2 - xy)} = -\frac{2}{xy} = -\frac{2}{v},$$

so that the condition of integrability by a factor of the form  $f(xy)$  is satisfied. Hence

$$\mu = e^{\int \frac{-2dv}{v}} = \frac{1}{v^2} = \frac{1}{x^2y^2}.$$

Multiplying the equation by this factor, and integrating, we find for the primitive

$$x^2 + \frac{1}{xy} + y^2 = C.$$

4. It is required to investigate the conditions under which the equation  $Mdx + Ndy = 0$  can be made integrable by a factor  $\mu$  which is a homogeneous function of  $x$  and  $y$  of the degree 0.

As  $\mu$  must be of the form  $\phi\left(\frac{y}{x}\right)$  let us represent  $\frac{y}{x}$  by  $v$ , and then assuming  $\mu = \phi(v)$ , and observing that

$$\frac{dv}{dx} = -\frac{y}{x^2}, \quad \frac{dv}{dy} = \frac{1}{x},$$

the partial differential equation (1) becomes

$$-N\phi'(v)\frac{y}{x^2} - M\phi'(v)\frac{1}{x} = \left(\frac{dM}{dy} - \frac{dN}{dx}\right)\phi(v) \dots\dots\dots (12),$$

whence 
$$\frac{\phi'(v)}{\phi(v)} = \frac{x^2 \left(\frac{dN}{dx} - \frac{dM}{dy}\right)}{Mx + Ny}.$$

Thus the condition sought is that the second member of the above equation should be a function of  $v$ , i.e. of  $\frac{y}{x}$ .

And the corresponding value of  $\mu$  is

$$\mu = e^{\int \frac{x^2 \left(\frac{dN}{dx} - \frac{dM}{dy}\right)}{Mx + Ny} dv}$$

But since every function of  $\frac{y}{x}$  is homogeneous and of the degree 0, with reference to the variables  $x$  and  $y$ , we may express the above results in the following theorem.

*In order that the equation  $Mdx + Ndy = 0$  may be made integrable by a factor  $\mu$  which is a homogeneous function of  $x$  and  $y$  of the degree 0, it is necessary and sufficient that the function*

$$\frac{x^2 \left(\frac{dN}{dx} - \frac{dM}{dy}\right)}{Mx + Ny} \dots\dots\dots (13)$$

*should be also homogeneous and of the degree 0. This condition being satisfied, the value of  $\mu$  will be*

$$\mu = e^{\int f(v) dv} \dots\dots\dots (14),$$

*where  $v$  stands for  $\frac{y}{x}$ , and  $f(v)$  is what the function (13) is reduced to by this transformation.*

The above investigation fails when the constitution of the functions  $M$  and  $N$  is such that we have *identically*

$$Mx + Ny = 0.$$

An integrating factor for this case has already been found in the preceding Chapter.

We proceed to notice some of the consequences of the above theorem.

It is evident that the condition which it involves will be satisfied when  $M$  and  $N$  are homogeneous functions of  $x$  and  $y$ . For, supposing them to be homogeneous and of the  $n^{\text{th}}$  degree, the numerator and denominator of the fraction (13) will each be of the  $(n+1)^{\text{th}}$  degree, and the fraction itself therefore of the degree 0, the condition required.

It is not however by homogeneous equations only that this condition is satisfied, and it is sometimes worth while to inquire into its applicability in other cases. Thus for the equation

$$\left(\frac{1}{y} + \sec \frac{y}{x}\right) dx - \frac{x}{y^2} dy = 0$$

we should find the integrating factor  $\cos \frac{y}{x}$ .

5. *It is required to investigate the conditions under which the equation  $Mdx + Ndy = 0$  can be made integrable by a factor  $\mu$ , which is a homogeneous function of the degree  $n$ .*

Assuming  $\mu = x^n \phi\left(\frac{y}{x}\right)$ , the partial differential equation (1) becomes

$$\begin{aligned} N \left\{ nx^{n-1} \phi\left(\frac{y}{x}\right) - x^{n-2} y \phi'\left(\frac{y}{x}\right) \right\} - Mx^{n-1} \phi'\left(\frac{y}{x}\right) \\ = \left( \frac{dM}{dy} - \frac{dN}{dx} \right) x^n \phi\left(\frac{y}{x}\right). \end{aligned}$$

Dividing by  $x^{n-2}$  and transposing, we get

$$(Mx + Ny) \phi'\left(\frac{y}{x}\right) = \left\{ x^2 \left( \frac{dN}{dx} - \frac{dM}{dy} \right) + nNx \right\} \phi\left(\frac{y}{x}\right)$$

whence

$$\frac{\phi'\left(\frac{y}{x}\right)}{\phi\left(\frac{y}{x}\right)} = \frac{x^2 \left( \frac{dN}{dx} - \frac{dM}{dy} \right) + nNx}{Mx + Ny}.$$

Let  $\frac{y}{x} = v$ , and suppose the second member to assume the form  $f(v)$ ; then, multiplying both sides by  $dv$  and integrating, we have

$$\log \phi(v) = \int f(v) dv.$$

$$\text{Hence } \mu = x^n \phi(v) = x^n e^{\int f(v) dv}.$$

Thus we arrive at the following theorem.

**THEOREM.** *In order that the equation  $Mdx + Ndy = 0$  may be made integrable by a factor  $\mu$ , which is a homogeneous function of  $x$  and  $y$  of the  $n^{\text{th}}$  degree, it is necessary, and it suffices, that on making  $y = vx$  the function*

$$\frac{x^3 \left( \frac{dN}{dx} - \frac{dM}{dy} \right) + nNx}{Mx + Ny} \dots\dots\dots (15)$$

*should assume the form  $f(v)$ . This condition being satisfied, the expression for  $\mu$  will be*

$$\mu = x^n e^{\int f(v) dv} \dots\dots\dots (16).$$

It will be noted that the condition that (15) shall be a function of  $v$ , is the same as the condition that it shall be a homogeneous function of  $x$  and  $y$  of the degree 0.

The theorem fails when  $Mx + Ny = 0$ , a case already considered.

**Ex. 1.** Required to determine whether the equation

$$(2x^3 + 3x^2y + y^2 - y^3) dx + (2y^3 + 3xy^2 + x^2 - x^3) dy = 0$$

admits of an integrating factor which is a homogeneous function of  $x$  and  $y$ .

Here  $M = 2x^3 + 3x^2y + y^2 - y^3$ ,  $N = 2y^3 + 3xy^2 + x^2 - x^3$ ,

$$\frac{dM}{dy} = 3x^2 + 2y - 3y^2, \quad \frac{dN}{dx} = 3y^2 + 2x - 3x^2,$$

$$\frac{dN}{dx} - \frac{dM}{dy} = 6y^2 - 6x^2 + 2x - 2y.$$

Hence, on substitution,

$$\begin{aligned} & \frac{x^2 \left( \frac{dN}{dx} - \frac{dM}{dy} \right) + nNx}{Mx + Ny} \\ &= \frac{-(n+6)x^4 + (3n+6)x^2y^2 + 2nxy^3 + (n+2)x^3 - 2x^2y}{2x^4 + 2x^3y + 2xy^3 + 2y^4 + x^2y + xy^2}. \end{aligned}$$

We are now to inquire whether there exists any value of  $n$  which reduces the second member of the above equation to a homogeneous function of  $x$  and  $y$  of the degree 0.

That member may be expressed in the form

$$\frac{-x}{x+y} \times \frac{(n+6)x^3 - (3n+6)xy^2 - 2ny^3 - (n+2)x^2 + 2xy}{2x^3 + 2y^3 + xy},$$

and it is now plain that if any value of  $n$  will answer the required condition, it must be one which will make the terms containing  $xy^2$  and  $x^2$  in the numerator of the second factor vanish. Making then  $n = -2$ , we have

$$\begin{aligned} \frac{-x}{x+y} \times \frac{4x^3 + 4y^3 + 2xy}{2x^3 + 2y^3 + xy} &= \frac{-2x}{x+y} \\ &= \frac{-2}{1+v}. \end{aligned}$$

$$\begin{aligned} \text{Hence } \mu &= x^{-2} e^{\int \frac{-2dv}{1+v}} = \frac{c}{x^2 (1+v)^2} \\ &= \frac{c}{(x+y)^2}. \end{aligned}$$

Multiplying the given equation by this factor and integrating, we find as the primitive equation

$$\frac{x^3 + xy + y^3}{x + y} = C.$$

In the case of homogeneous equations the condition involved in the general theorem will be satisfied *independently of the value of  $n$* , the particular case in which  $Mx + Ny = 0$  excepted. It follows hence that with this exception we can find an integrating factor of any proposed degree for the homogeneous equation  $Mdx + Ndy = 0$ .

Ex. 2. Required two integrating factors of the respective degrees 0 and 1 for the equation

$$(3x + 2y) dx + xdy = 0.$$

First making  $M = 3x + 2y$ ,  $N = x$ , and  $n = 0$ , we have

$$\frac{x^2 \left( \frac{dN}{dx} - \frac{dM}{dy} \right) + nNx}{Mx + Ny} = \frac{-x}{3(x+y)}.$$

Hence 
$$f(v) = \frac{-1}{3(1+v)},$$

$$\mu = e^{\int f(v) dv} = c(v+1)^{-\frac{1}{3}} = c \left( \frac{x}{x+y} \right)^{\frac{1}{3}}.$$

Secondly, making  $M = 3x + 2y$ ,  $N = x$ ,  $n = 1$ , we have

$$\frac{x^2 \left( \frac{dN}{dx} - \frac{dM}{dy} \right) + Nx}{Mx + Ny} = 0.$$

Hence 
$$f(v) = 0,$$

$$\mu = x e^{\int f(v) dv} = c'x.$$

Thus replacing each of the constants  $c$  and  $c'$  by unity, the integrating factors in question are  $\left( \frac{x}{x+y} \right)^{\frac{1}{3}}$  and  $x$ .

Multiplying by the second factor  $x$  and integrating, we find  $x^3 + x^2y = C$  for the primitive.

Again, if in illustration of the remark of Art. 4, Chap. IV., we equate to an arbitrary constant the ratio of the second factor to the first, we have

$$x^{\frac{2}{3}}(x + y)^{\frac{1}{3}} = \text{constant},$$

which being equivalent to

$$x^2(x + y) = \text{constant},$$

agrees with the previous solution.

Let us next examine the *general* results to which the theorem leads, when  $M$  and  $N$  are homogeneous and of the  $m^{\text{th}}$  degree.

The general forms of  $M$  and  $N$  will be on putting  $v$  for  $\frac{y}{x}$ ,

$$M = x^m \phi(v), \quad N = x^m \psi(v).$$

Hence, observing that

$$\frac{dN}{dx} = mx^{m-1}\psi(v) - x^{m-2}y\psi'(v),$$

$$\frac{dM}{dy} = x^{m-1}\phi'(v);$$

we have on substituting in the expression for  $f(v)$ , and dividing numerator and denominator of the result by  $x^{m+1}$ ,

$$f(v) = \frac{(m+n)\psi(v) - v\psi'(v) - \phi'(v)}{\phi(v) + v\psi(v)} \dots\dots\dots(17).$$

If we make  $n$ , the value of which may be chosen at pleasure, equal to  $-m-1$ , we have

$$f(v) = -\frac{\psi(v) + v\psi'(v) + \phi'(v)}{\phi(v) + v\psi(v)}.$$

Multiplying by  $dv$  and integrating,

$$\int f(v) dv = -\log \{\phi(v) + v\psi(v)\},$$

$$\text{Hence, } \mu = x^n e^{\int f(v) dv} = \frac{C}{x^{m+1} \{\phi(v) + v\psi(v)\}} = \frac{C}{Mx + Ny} \dots (18).$$

And here again it results that the homogeneous equation  $Mdx + Ndy = 0$ , may be made integrable by the factor  $\frac{1}{Mx + Ny}$ , except in the particular case in which the constitution of  $M$  and  $N$  is such as to make  $Mx + Ny = 0$ . Moreover this theorem is seen to be only a particular consequence of the *general* theory of the integrating factors of homogeneous equations.

Resuming (17) which we may write in the form

$$f(v) = \frac{(m+n+1)\psi(v) - \{\psi(v) + v\psi'(v) + \phi'(v)\}}{\phi(v) + v\psi(v)},$$

we have

$$\int f(v) dv = (m+n+1) \int \frac{\psi(v) dv}{\phi(v) + v\psi(v)} - \log \{\phi(v) + v\psi(v)\},$$

by the substitution of which, combined with the previous reduction, the *general* value of  $\mu$  becomes

$$\mu = \frac{x^{m+n+1} e^{(m+n+1) \int \frac{\psi(v) dv}{\phi(v) + v\psi(v)}}}{Mx + Ny} \dots (19),$$

which is the general expression for an integrating factor of the  $n^{\text{th}}$  degree, supposing  $n$  *not* equal to  $-m-1$ .

If we now equate to an arbitrary constant the ratio borne by the last value of  $\mu$  to the previous one (18), we have

$$x^{m+n+1} e^{(m+n+1) \int \frac{\psi(v) dv}{\phi(v) + v\psi(v)}} = C,$$

which is readily reducible to

$$\log x + \int \frac{\psi(v) dv}{\phi(v) + v\psi(v)} = C \dots (20).$$

Now this is the very solution of the homogeneous equation  $Mdx + Ndy = 0$ , obtained by the direct assumption  $y = vx$ , in Art. 8, Chap. II.

We thus see that in the case of homogeneous equations the employment of integrating factors conducts us, but by a more lengthened route, to the same *final* integrals as the direct method of Chap. II. It is difficult to lay down any general rule as to the value of concurrent methods, but it would probably be not very remote from truth to say, that the *peculiar* advantage of the theory of integrating factors consists rather in its appropriateness for the investigation of conditions under which solution is possible, than in the actual processes of solution to which it leads.

6. The following application of the theorem is of a more general character.

The equation

$$P_1 dx + P_2 dy + Q (xdy - ydx) = 0 \dots\dots\dots (21),$$

where  $P_1$  and  $P_2$  are homogeneous functions of  $x$  and  $y$  of the degree  $p$ , and  $Q$  is a homogeneous function of  $x$  and  $y$  of the degree  $q$ , may be rendered integrable by a factor  $\mu$  which is a homogeneous function of  $x$  and  $y$  of the degree  $-q - 2$ .

$$\text{Here } M = P_1 - Qy, \quad N = P_2 + Qx.$$

$$\text{Hence } Mx + Ny = P_1x + P_2y.$$

Thus the denominator of (15) is the same as if  $M$  and  $N$  were reduced to their first terms  $P_1$  and  $P_2$ . And the numerator remains the same also. For the addition which the second terms of  $M$  and  $N$ , viz.  $-Qy$  and  $Qx$ , make thereto is

$$x^2 \left\{ \frac{d}{dx}(Qx) + \frac{d}{dy}(Qy) \right\} + nQx^2,$$

which, on effecting the differentiation, becomes

$$x^2 \left\{ x \frac{dQ}{dx} + y \frac{dQ}{dy} + (n+2) Q \right\},$$

but  $Q$  being by hypothesis homogeneous of the  $q^{\text{th}}$  degree, whence,

$$x \frac{dQ}{dx} + y \frac{dQ}{dy} = qQ,$$

the above expression reduces to

$$x^2 (q + n + 2) Q,$$

and vanishes if  $n$  is made equal to  $-q - 2$ . Thus (15) assumes the same form as if  $M$  and  $N$  were homogeneous of the degree  $p$ , and the condition of the theorem is satisfied.

[If we write equation (21) in the form

$$P_1 dx + P_2 dy + Qx^2 d\frac{y}{x} = 0,$$

the required result follows at once from the remark on page 79, lines 4...7; for a homogeneous factor of the degree  $-q - 2$  will obviously render  $Qx^2 d\frac{y}{x}$  integrable.]

7. All the applications which we have hitherto made of the partial differential equation (1) are of one kind. The general problem which they exemplify is the following. Under what condition does the equation  $Mdx + Ndy = 0$  admit of being made integrable by a factor of the form  $\phi(v)$  where  $v$  is a known and definite function of  $x$  and  $y$ ? Let us examine the general form of its solution.

On substituting  $\phi(v)$  for  $\mu$  in (1), we find

$$\frac{\phi'(v)}{\phi(v)} = \frac{\frac{dM}{dy} - \frac{dN}{dx}}{N\frac{dv}{dx} - M\frac{dv}{dy}} \dots\dots\dots (22).$$

The condition sought then is that the second member of this equation should be a function of  $v$ . Representing that function by  $f(v)$  the corresponding value of  $\mu$  is

$$\mu = e^{\int f(v) dv} \dots\dots\dots (23).$$

Any special case may be treated either independently as in the previous examples, or by directly referring it to the above general form.

Thus a direct reference to the above theorem shews that the condition which must be satisfied in order that the equation  $Mdx + Ndy = 0$  may admit of an integrating factor of the form  $\phi(x^2 + y)$  is that the function

$$\frac{\frac{dM}{dy} - \frac{dN}{dx}}{2Nx - M}$$

should be a function of  $x^2 + y$ . And the mode of determining this point would be to assume  $x^2 + y = v$ , and, thence deducing  $y = v - x^2$ , to substitute that value of  $y$  in the above function, and see whether the result assumed the form  $f(v)$ . The equation (23) would then give the value of  $\mu$ . And this mode of procedure is general.

8. When by the discovery of an integrating factor the possibility of solving a differential equation has been established, there is no more valuable exercise than to endeavour to effect the same object by other means.

Let us take as an example the equation considered in Art. 6, viz.

$$P_1 dx + P_2 dy + Q (x dy - y dx) = 0 \dots\dots\dots (24),$$

$P_1$  and  $P_2$  being homogeneous of the degree  $p$ , and  $Q$  homogeneous of the degree  $q$ .

Let  $P_1 = x^p \phi\left(\frac{y}{x}\right)$ ,  $P_2 = x^p \psi\left(\frac{y}{x}\right)$ ,  $Q = x^q \chi\left(\frac{y}{x}\right)$ , then making  $\frac{y}{x} = v$ , whence flow

$$dy = x dv + v dx,$$

$$x dy - y dx = x^2 dv,$$

the given equation, expressed in terms of the variables  $x$  and  $v$ , becomes

$$x^p \phi(v) dx + x^p \psi(v) (x dv + v dx) + x^q \chi(v) \times x^2 dv = 0,$$

and assumes on transposition and division the form

$$\frac{dx}{dv} + \frac{\psi(v)}{\phi(v) + v\psi(v)} x = - \frac{\chi(v)}{\phi(v) + v\psi(v)} \times x^{q-p+2} \dots\dots (25).$$

Now the reducibility of an equation of this form to a linear form has been established in Chap. II. Art. 11.

Under the general form (24) are virtually included some remarkable equations which have been made the subjects of distinct investigations.

Thus Jacobi has, by an analysis of a very peculiar character, solved the differential equation (Crelle's *Journal*, Vol. XXIV.)

$$(A + A'x + A''y)(xdy - ydx) - (B + B'x + B''y)dy + (C + C'x + C''y)dx = 0 \dots\dots\dots (26).$$

If, however, we assume in that equation

$$x = \xi + \alpha, \quad y = \eta + \beta,$$

we can, by a proper determination of the constants  $\alpha$  and  $\beta$ , reduce it to the form

$$(a\xi + a'\eta)(\xi d\eta - \eta d\xi) - (b\xi + b'\eta)d\eta + (c\xi + c'\eta)d\xi = 0,$$

which falls under (24). On effecting the substitution in question the equations for determining  $\alpha$  and  $\beta$  will be found to be

$$\begin{aligned} \alpha(A + A'\alpha + A''\beta) - (B + B'\alpha + B''\beta) &= 0, \\ -\beta(A + A'\alpha + A''\beta) + C + C'\alpha + C''\beta &= 0. \end{aligned}$$

The most convenient mode of solving these equations is to write them in the symmetrical form

$$\frac{B + B'\alpha + B''\beta}{\alpha} = \frac{C + C'\alpha + C''\beta}{\beta} = A + A'\alpha + A''\beta,$$

then, equating each of these expressions to  $\lambda$ , we find

$$\begin{aligned} A - \lambda + A'\alpha + A''\beta &= 0, \\ B + (B' - \lambda)\alpha + B''\beta &= 0, \\ C + C'\alpha + (C'' - \lambda)\beta &= 0, \end{aligned}$$

from which eliminating  $\alpha$  and  $\beta$  we have the cubic equation

$$(A - \lambda)(B' - \lambda)(C'' - \lambda) - B''C'(A - \lambda) - A''C(B' - \lambda) - A'B(C'' - \lambda) + A'B''C + A''BC' = 0 \dots\dots\dots (27).$$

If a value of  $\lambda$  be found from this equation, any two equations of the preceding system will give  $\alpha$  and  $\beta$ .

9. The present chapter would be incomplete without some notice of a method which was largely employed by Euler.

That method consisted in assuming  $\mu$  to be a function definite in form as respects the variable  $y$ , but involving unknown functions of  $x$  as the coefficients of the several powers of  $y$ .

After the substitution of this form of  $\mu$  in the partial differential equation (1), the result is arranged according to the powers of  $y$ , and the coefficients of those powers separately equated to 0. This gives a series of simultaneous differential equations for the determination of the unknown functions of  $x$ . But for the success of the method it is necessary that the primary assumption for  $\mu$  should have been chosen with some special fitness to the object proposed. The following is an example.

Required the conditions under which the equation

$$Pydx + (y + Q)dy = 0$$

admits of being made integrable by a factor of the form

$$\frac{1}{y^3 + Ry^2 + Sy},$$

$P$ ,  $Q$ ,  $R$  and  $S$  being functions of  $x$ .

In the partial differential equation (1), making

$$M = Py, \quad N = y + Q, \quad \mu = \frac{1}{y^3 + Ry^2 + Sy},$$

clearing the result of fractions and arranging it according to the powers of  $y$ , we have

$$\begin{aligned} \left(2P + \frac{dQ}{dx} - \frac{dR}{dx}\right) y^3 + \left(PR + R \frac{dQ}{dx} - Q \frac{dR}{dx} - \frac{dS}{dx}\right) y^2 \\ + \left(S \frac{dQ}{dx} - Q \frac{dS}{dx}\right) y = 0 \dots\dots\dots (28). \end{aligned}$$

Whence, equating separately to 0 the coefficients of the different powers of  $y$ , we have the ternary system

$$2P + \frac{dQ}{dx} - \frac{dR}{dx} = 0 \dots\dots\dots (29),$$

$$PR + R \frac{dQ}{dx} - Q \frac{dR}{dx} - \frac{dS}{dx} = 0 \dots\dots\dots (30),$$

$$S \frac{dQ}{dx} - Q \frac{dS}{dx} = 0 \dots\dots\dots (31).$$

The last equation gives  $S = cQ$ ,  $c$  being an arbitrary constant. Substituting this value of  $S$  in the equation obtained by eliminating  $P$  from the first two equations of the system, we find

$$(2c - R) dQ + 2QdR = R dR,$$

or, regarding therein  $R$  as the independent and  $Q$  as the dependent variable,

$$(2c - R) \frac{dQ}{dR} + 2Q = R,$$

a linear equation of which the solution is

$$Q = R - c + c' (R - 2c)^2.$$

Hence we have

$$S = c (R - c) + cc' (R - 2c)^2,$$

and from the substitution of the value of  $Q$  in the first equation of the ternary system,

$$P = -c' (R - 2c) \frac{dR}{dx}.$$

These values of  $S$ ,  $Q$ , and  $P$ , in which  $R$  is arbitrary, reduce the given differential equation to the form

$$\{R - c + c' (R - 2c)^2 + y\} dy - c'y (R - 2c) dR = 0 \dots (32),$$

and present its integrating factor in the form

$$\frac{1}{y^3 + Ry^2 + \{c(R - c) + cc'(R - 2c)^2\}y},$$

$R$  being an arbitrary function of  $x$ .

For other examples the student is referred to Lacroix (*Traité du Calcul Diff. et du Calcul Int.* Vol. II. Chap. IV.). The results of this method are usually of a very complex character, while their generality is limited by the restrictions which must be imposed in order to render the system of reducing equations solvable. Thus Euler's equation above considered is virtually only a limited case of the general equation (21). If we assume

$$y + c = s, \quad R - 2c = t,$$

it becomes

$$(s + t) ds + cc' t dt + c't (t ds - s dt),$$

which evidently falls under that equation.

[The Jacobian theory of the Last Multiplier, which is connected with the subject of the present Chapter, is discussed in the *Supplementary Volume*, Chapter XXXI.]

### EXERCISES.

1. The following equations admit of integrating factors of the form  $\phi(x)$ , viz.

$$(1) \quad (x^2 + y^2 + 2x) dx + 2y dy = 0.$$

$$(2) \quad (x^2 + y^2) dx - 2xy dy = 0.$$

Determine these factors and integrate the equations.

2. The equation  $2xy dx + (y^2 - 3x^2) dy = 0$  has an integrating factor which is a function of  $y$ . Determine it, and integrate the equation.

3. Find those integrating factors of the equation

$$ydx + (2y - x) dy = 0$$

which are homogeneous functions of  $x$  and  $y$  of the respective degrees 0 and  $-2$ , and from the consideration of those factors deduce the complete primitive of the equation.

4. For each of the following equations examine whether there exists an integrating factor  $\mu$  satisfying the particular condition specified, and if so determine the factor, and integrate the equation.

(1)  $y(x^2 + y^2) dx + x(xdy - ydx) = 0$ ,  $\mu$  a homogeneous function of the degree  $-3$ .

(2)  $(y^3 + axy^2) dy - ay^3 dx + (x + y)(xdy - ydx) = 0$ ,  $\mu$  as in the previous example.

(3)  $(y - x) dy + ydx - xd\left(\frac{x}{y}\right) = 0$ ,  $\mu$  homogeneous of the degree  $-1$ .

(4)  $(x^2 + y^2 + 1) dx - 2xydy = 0$ ,  $\mu$  a function of  $y^2 - x^2$ .

(5)  $(y - 3x^2y^3 - 2x^3) dx + (2y^3 + 3x^3y^2 - x) dy = 0$ ,  $\mu$  a function of  $x^3 + y$ .

(6)  $(x^2 + x^2y + 2xy - y^2 - y^3) dx + (y^2 + xy^2 + 2xy - x^2 - x^3) dy = 0$ ,  $\mu$  a function of the product  $(1 + x)(1 + y)$ .

(7)  $(3y^2 - x) dx + (2y^3 - 6xy) dy = 0$ ,  $\mu$  a function of  $x + y^2$ .

5. The equation  $y(x^2 + y^2) dx + x(xdy - ydx) = 0$  has an integrating factor of the form  $e^x \phi(x^2 + y^2)$ . Determine it, and, from the comparison of the result with that of (1) Ex. 4, deduce the complete primitive.

6. The linear equation  $\frac{dy}{dx} + Py = Q$  having an integrating factor of the form  $e^{\int P dx}$ , deduce a corresponding expression for an integrating factor of the equation

$$\frac{dy}{dx} + Py = Qy^n.$$

7. Prove that the equation

$$\frac{dy}{dx} + y^2 = \frac{dP}{dx} + P^2,$$

where  $P$  is any function of  $x$ , has an integrating factor of the form  $\frac{e^{-2\int P dx}}{(y-P)^2}$ . Lacroix, Tom. II. p. 278.

8. Deduce a similar expression for an integrating factor of the equation  $\frac{dy}{dx} + y^2 + \frac{dP}{dx} + P^2 = 0$ . *Ib.*

9. Investigate the conditions under which the equation

$$\frac{dy}{dx} + \frac{P}{y} = Q,$$

where  $P$  and  $Q$  are functions of  $x$ , can be made integrable by a factor of the form  $\frac{y}{\{y + f(x)\}^n}$ , and determine the form of  $f(x)$ .

## CHAPTER VI.

### OF SOME REMARKABLE EQUATIONS OF THE FIRST ORDER AND DEGREE.

1. THERE are certain differential equations of the first order and degree, to which, in addition to their intrinsic claims upon our notice, some degree of historical interest belongs. Among such, a prominent place is due to two equations which, having been first discussed by the Italian mathematician Riccati and by Euler respectively, have from this circumstance derived their names. To these equations, and to some other allied forms, the present Chapter will be devoted.

Riccati's equation is usually expressed in the form

$$\frac{du}{dx} + bu^2 = cx^m \dots\dots\dots (1).$$

But as both it and some other equations closely related to it and possessing a distinct interest, may, either immediately or after a slight reduction, be referred to the more general equation

$$x \frac{dy}{dx} - ay + by^2 = cx^n \dots\dots\dots (2),$$

the discussion of which happens to be much more easy than that of the special equations which are included under it, we shall consider this equation first.

To reduce Riccati's equation under the general form (2), it suffices to assume  $u = \frac{y}{x}$ . We find, as the result of this substitution in (1),

$$x \frac{dy}{dx} - y + by^2 = cx^{n+2} \dots\dots\dots (3),$$

which is seen to be a particular case of (2).

*Of the equation  $x \frac{dy}{dx} - ay + by^2 = cx^n$ .*

2. The discussion upon which we are entering may be divided into two parts. First, we shall shew that the equation is solvable when  $n = 2a$ . Secondly, we shall establish a series of transformations by which a corresponding series of other cases may be reduced to the above.

3. First. The equation  $x \frac{dy}{dx} - ay + by^2 = cx^n$  is solvable when  $n = 2a$ .

For, assuming  $y = x^a v$ , we find on substitution

$$x^{a+1} \frac{dv}{dx} + bx^{2a}v^2 = cx^n,$$

whence, dividing by  $x^{2a}$ , we have

$$x^{1-a} \frac{dv}{dx} + bv^2 = cx^{n-2a}.$$

Now if  $n = 2a$  the above becomes

$$x^{1-a} \frac{dv}{dx} + bv^2 = c,$$

whence

$$\frac{dv}{c - bv^2} = \frac{dx}{x^{1-a}},$$

an equation in which the variables are separated. If we restore to  $v$  its value  $\frac{y}{x^a}$  and transpose, this becomes

$$\frac{x^a dy - ayx^{a-1} dx}{by^2 - cx^{2a}} + x^{a-1} dx = 0 \dots \dots \dots (4),$$

an exact differential equation, of which the solution will be

$$y = \left(\frac{c}{b}\right)^{\frac{1}{2}} x^a \frac{C \epsilon^{\frac{2(bc)^{\frac{1}{2}} x^a}{a}} + 1}{C \epsilon^{\frac{2(bc)^{\frac{1}{2}} x^a}{a}} - 1},$$

or 
$$y = \left(-\frac{c}{b}\right)^{\frac{1}{2}} x^a \tan \left\{ C - \frac{(-bc)^{\frac{1}{2}} x^a}{a} \right\},$$

according as  $b$  and  $c$  have like or have unlike signs.

4. Secondly. The solution of the equation

$$x \frac{dy}{dx} - ay + by^2 = cx^n$$

is always reducible by transformation to the preceding case whenever  $\frac{n \pm 2a}{2n} = i$ , a positive integer.

For let  $y = A + \frac{x^n}{y_1}$ ,  $y_1$  being a new variable which is to replace  $y$ , and  $A$  a constant whose value is yet to be determined. On substitution and arrangement of the terms we have

$$-aA + bA^2 + (n - a + 2bA) \frac{x^n}{y_1} + b \frac{x^{2n}}{y_1^2} - \frac{x^{n+1}}{y_1^2} \frac{dy_1}{dx} = cx^n \dots (5).$$

Now let  $-aA + bA^2 = 0$ , then  $A = \frac{a}{b}$  or 0. These values of  $A$  we shall employ in succession.

5. First. If we assume  $A = \frac{a}{b}$  the above equation becomes

$$(n + a) \frac{x^n}{y_1} + b \frac{x^{2n}}{y_1^2} - \frac{x^{n+1}}{y_1^2} \frac{dy_1}{dx} = cx^n.$$

Multiplying this equation by  $\frac{y_1^2}{x^n}$  and transposing, we have

$$x \frac{dy_1}{dx} - (a + n) y_1 + cy_1^2 = bx^n \dots \dots \dots (6).$$

Now this equation is of the same *form* as the given equation between  $y$  and  $x$ . The coefficients however differ, in that  $b$  and  $c$  have changed their places, and  $a$  has become  $a + n$ . And this transformation has been effected by the assumption

$$y = \frac{a}{b} + \frac{x^n}{y_1}.$$

Hence, if in the transformed equation (6) we make a second assumption

$$y_1 = \frac{a + n}{c} + \frac{x^n}{y_2},$$

we shall have as the result

$$x \frac{dy_2}{dx} - (a + 2n) y_2 + b y_2^2 = c x^n \dots \dots \dots (7),$$

$b$  and  $c$  again changing places, and  $a + n$  becoming  $a + 2n$ . And the result of  $i$  successive transformations of the same series will be to reduce the given equation either to the form

$$x \frac{dy_i}{dx} - (a + in) y_i + c y_i^2 = b x^n \dots \dots \dots (8),$$

or to the form

$$x \frac{dy_i}{dx} - (a + in) y_i + b y_i^2 = c x^n \dots \dots \dots (9),$$

according as the integer  $i$  is odd or even.

Now by what has been established in Art. 3 the above equations will be integrable if we have

$$n = 2(a + in),$$

an equation which gives

$$\frac{n - 2a}{2n} = i \dots \dots \dots (10).$$

6. Secondly. If we assign to  $A$  its second value 0, (5) becomes

$$(n - a) \frac{x^n}{y_1} + b \frac{x^{2n}}{y_1^2} - \frac{x^{n+1}}{y_1^2} \frac{dy_1}{dx} = c x^n.$$

Or, multiplying by  $\frac{y_1^2}{x^n}$  and transposing,

$$x \frac{dy_1}{dx} - (n - a) y_1 + c y_1^2 = b x^n \dots \dots \dots (11).$$

Now this equation for  $y_1$  differs from the equation (6) obtained for  $y_1$  in the previous series of transformations only in that  $a$  in the coefficient of the second term has become  $-a$ . With this change only then that series of transformations may be adopted in the present instance. The change of  $a$  into  $-a$  in the final condition (10) gives

$$\frac{n + 2a}{2n} = i$$

as a new condition under which the equation in  $y$  is solvable. If  $i = 1$  this gives  $n = 2a$ , the condition first arrived at, and upon which the subsequent researches were based.

Collecting these results together we see that *the equation*  $x \frac{dy}{dx} - ay + by^2 = cx^n$  *is integrable whenever*  $\frac{n \pm 2a}{2n}$  *is a positive integer.*

7. Let us now examine the form in which the solution is presented.

If  $\frac{n - 2a}{2n} = i$ , which is the condition arrived at in Art. 5, we have the series of transformations

$$y = \frac{a}{b} + \frac{x^n}{y_1},$$

$$y_1 = \frac{a + n}{c} + \frac{x^n}{y_2},$$

$$y_2 = \frac{a + 2n}{b} + \frac{x^n}{y_3},$$

and finally

$$y_{i-1} = \frac{a + (i - 1)n}{k} + \frac{x^n}{y_i},$$

where  $k = b$  or  $c$ , according as  $i$  is odd or even; and the effect of these transformations is to reduce the given equation to one or the other of the forms (8) and (9).

If in the above expression for  $y$  we substitute for  $y_1$  its value in terms of  $y_2$ , in that result again, for  $y_2$  its value in terms of  $y_3$ , and so on, we find

$$y = \frac{a}{b} + \frac{x^n}{\frac{a+n}{c} + \frac{x^n}{\frac{a+2n}{b} \dots \dots \dots (A)},$$

the last denominator being  $\frac{a + (i-1)n}{k} + \frac{x^n}{y_i}$ . The value of  $y_i$  must then be determined by the solution of (8) or of (9), these equations being now susceptible of expression as exact differential equations in the forms

$$\frac{x^{a+in} dy_i - (a+in) y_i x^{a+in-1} dx}{cy_i^2 - bx^n} + x^{a+in-1} dx = 0 \dots \dots (B),$$

$$\frac{x^{a+in} dy_i - (a+in) y_i x^{a+in-1} dx}{by_i^2 - cx^n} + x^{a+in-1} dx = 0 \dots \dots (C).$$

When therefore  $\frac{n-2a}{2n} = i$  a positive integer, the solution of the equation  $x \frac{dy}{dx} - ay + by^2 = cx^n$  will be expressed in the form of a continued fraction by (A), the value of  $y_i$  in the last denominator being given by the solution of the exact differential equation (B) or (C) according as  $i$  is odd or even.

Secondly, if  $\frac{n+2a}{2n} = i$ , which is the condition arrived at in Art 6, we have the series of transformations

$$y = \frac{x^n}{y_1},$$

$$y_1 = \frac{n-a}{c} + \frac{x^n}{y_2},$$

$$y_2 = \frac{2n - a}{b} + \frac{x^n}{y_3},$$

.....

$$y_{i-1} = \frac{(i-1)n - a}{k} + \frac{x^n}{y_i} \dots\dots\dots (12),$$

where  $k = b$  or  $c$ , according as  $i$  is odd or even. From these, eliminating, as before, the intermediate variables  $y_1, y_2, \dots, y_{i-1}$ , we find

$$y = \frac{x^n}{\frac{n-a}{c} + \frac{2n-a}{b} + \frac{x^n}{\frac{3n-a}{c}} \dots\dots\dots (1)},$$

the last denominator being  $\frac{(i-1)n - a}{k} + \frac{x^n}{y_i}$ . In this case, however, the equation for  $y_i$  formed by changing  $a$  into  $-a$  in  $B$  and  $C$  will be

$$\frac{x^{in-a} dy_i - (in - a) y_i x^{in-a-1} dx}{cy_i^2 - bx^n} + x^{in-a-1} dx = 0 \dots\dots\dots (E),$$

or  $\frac{x^{in-a} dy_i - (in - a) y_i x^{in-a-1} dx}{by_i^2 - cx^n} + x^{in-a-1} dx = 0 \dots\dots\dots (F),$

according as  $i$  is odd or even.

When therefore  $\frac{n+2a}{2n} = i$  a positive integer, the solution of  $x \frac{dy}{dx} - ay + by^2 = cx^n$  is expressed by (D), the value of  $y_i$  in the last denominator being given by the exact differential equation (E) or (F) according as  $i$  is odd or even.

Ex. Given  $x \frac{dy}{dx} - y + y^2 = x^{\frac{1}{2}}$ .

Here  $n = \frac{2}{3}$ ,  $\alpha = 1$ , and as  $\frac{n+2\alpha}{2n} = 2$  while  $\frac{n-2\alpha}{2n} = -1$ , the formulæ (D) and (F) must be employed. Assuming therein  $\alpha = 1$ ,  $b = 1$ ,  $c = 1$ ,  $n = \frac{2}{3}$ ,  $i = 2$ , we have

$$y = \frac{x^{\frac{2}{3}}}{-\frac{1}{3} + \frac{x^{\frac{2}{3}}}{y_2}} = \frac{3x^{\frac{2}{3}}y_2}{3x^{\frac{2}{3}} - y_2} \dots\dots\dots(13),$$

$y_2$  being given by the exact differential equation

$$\frac{x^{\frac{1}{3}}dy_2 - \frac{1}{3}y_2x^{-\frac{2}{3}}dx}{y_2^2 - x^{\frac{2}{3}}} + x^{-\frac{2}{3}}dx = 0 \dots\dots\dots(14),$$

from which we find

$$\frac{1}{2} \log \left( \frac{y_2 - x^{\frac{1}{3}}}{y_2 + x^{\frac{1}{3}}} \right) + 3x^{\frac{1}{3}} = C \dots\dots\dots(15).$$

The elimination of  $y_2$  between (13) and (15) gives

$$\log \frac{3yx^{\frac{1}{3}} - 3x^{\frac{2}{3}} - y}{3yx^{\frac{1}{3}} + 3x^{\frac{2}{3}} + y} + 6x^{\frac{1}{3}} = C \dots\dots\dots(16),$$

which is the complete primitive.

Ex. 2. Given  $\frac{du}{dx} + u^2 = x^{-\frac{4}{3}}$ .

This is an example of Riccati's equation. Assuming therefore  $u = \frac{y}{x}$ , we find  $x \frac{dy}{dx} - y + y^2 = x^{\frac{2}{3}}$ , which is identical with the equation last considered. Substituting therefore in (16)  $ux$  for  $y$ , we find after reduction

$$\log \frac{3ux^{\frac{2}{3}} - 3 - ux^{\frac{1}{3}}}{3ux^{\frac{2}{3}} + 3 + ux^{\frac{1}{3}}} + 6x^{\frac{1}{3}} = C \dots\dots\dots(17).$$

*General Observations.*

8. The connexion between the two conditions for the solution of the equation  $x \frac{dy}{dx} - ay + by^2 = cx^n$ , implied by the double sign in the equation  $\frac{n \pm 2a}{2n} = i$ , may otherwise be established as follows.

If the differential equation be written in the form

$$x \frac{dy}{dx} + by \left( y - \frac{a}{b} \right) = cx^n \dots \dots \dots (18),$$

it becomes evident that it is symmetrical with respect to  $y$  and  $y - \frac{a}{b}$ . Assume then  $y - \frac{a}{b}$  as a new variable in place of  $y$ , and writing  $y - \frac{a}{b} = y'$ ,  $y = y' + \frac{a}{b}$ , the equation becomes

$$x \frac{dy'}{dx} + b \left( y' + \frac{a}{b} \right) y' = cx^n \dots \dots \dots (19),$$

or 
$$x \frac{dy'}{dx} + ay' + by'^2 = cx^n \dots \dots \dots (20),$$

an equation which differs from the given equation only in that  $y$  has become  $y'$ , and  $a$  has changed its sign. Hence the conditions  $n = \frac{-2a}{2i-1}$  and  $n = \frac{2a}{2i-1}$  are mutually dependent, and the value of  $y$  having been obtained for the former case, its value in the latter will be found by changing therein  $a$  into  $-a$ , and finally adding  $\frac{a}{b}$ .

It is here also to be noted that instead of beginning with an assumption of the form  $y = A + \frac{x^n}{y_1}$  as in Art. 4, we might have commenced our reductions by the assumption  $y = \frac{x^n}{B + y_1}$ , the former of the above being proper for increasing by  $n$ , the

latter for diminishing by  $n$  the quantity  $\alpha$ . And as the first led *directly* to the solution (A), so would the second have led directly to the solution (D).

Lastly, it may be remarked that each of the above assumptions is only the *inverse* of the other. To increase the value of  $\alpha$  by  $n$  we had to employ the assumption

$$y_{i-1} = A + \frac{x^n}{y_i},$$

which gives

$$y_i = \frac{x^n}{-A + y_{i-1}},$$

and this indicates the form of the assumption for the case in which  $\alpha$  is to be diminished. Hence also by admitting negative as well as positive values of  $i$ , the two forms of solution might be replaced by a single one.

9. We have seen in Art. 1 that Riccati's equation

$$\frac{du}{dx} + bu^2 = cx^m$$

is reduced by the assumption  $u = \frac{y}{x}$  to the form

$$x \frac{dy}{dx} - y + by^2 = cx^{m+2}.$$

Hence the condition for the solution of Riccati's equation, found by substituting in the final theorem of Art. 6, 1 for  $\alpha$  and  $m+2$  for  $n$ , will be

$$\frac{m+2 \pm 2}{2m+4} = i,$$

whence

$$m = -2 \pm \frac{2}{2i-1} \dots\dots\dots (21),$$

$i$  being a positive integer.

We may give to the expression for  $m$  another form, viz.  $m = \frac{-4i}{2i \pm 1}$ ,  $i$  admitting of the value 0 together with positive integral values. In order to prove this, let it be observed that two values of  $m$  included in (21) are

$$m = \frac{-4i}{2i-1}, \text{ and } m = \frac{-4(i-1)}{2i-1}.$$

If in the second of these values we change  $i-1$  into  $i$ , and therefore  $i$  into  $i+1$ , a change which merely involves that we interpret  $i$  as admitting of the value 0 as well as of positive integral values, we find

$$m = \frac{-4i}{2i+1} \dots\dots\dots (22).$$

When  $i=0$  this gives  $m=0$ , and as this value also results from the first of the expressions for  $m$  on making  $i=0$ , we are permitted in that formula also to regard  $i$  as admitting of the same range of values. Hence, combining the two formulæ in a single expression, we have

$$m = \frac{-4i}{2i \pm 1} \dots\dots\dots (23),$$

$i$  being 0, or a positive integer.

10. Riccati's equation may also be reduced, and it usually has been reduced, by a series of *double* transformations, of which the following will serve as an example.

The equation being  $\frac{du}{dx} + bu^2 = cx^m$ , let  $u = \frac{1}{bx} + \frac{1}{x^2u_1}$ .

We have

$$\frac{du}{dx} = -\frac{1}{bx^2} - \frac{2}{x^3u_1} - \frac{1}{x^2u_1^2} \frac{du_1}{dx},$$

$$bu^2 = \frac{1}{bx^2} + \frac{2}{x^3u_1} + \frac{b}{x^4u_1^2}.$$

Substituting these values in the given equation, we have

$$\frac{b}{x^4 u_1^2} - \frac{1}{x^2 u_1^2} \frac{du_1}{dx} = cx^m.$$

Whence,

$$x^2 \frac{du_1}{dx} + cx^{m+4} u_1^2 - b = 0.$$

In this equation assume  $x = z^{\frac{1}{m+3}}$ , then

$$\frac{du_1}{dx} = \frac{du_1}{dz} \frac{dz}{dx} = (m+3) z^{\frac{m+2}{m+3}} \frac{du_1}{dz},$$

whence, after substitution and reduction,

$$\frac{du_1}{dz} + \frac{c}{m+3} u_1^2 = \frac{b}{m+3} z^{-\frac{m+4}{m+3}} \dots\dots\dots (24),$$

an equation differing from the given equation, as to its coefficients and indices, in that  $b$  has been converted into  $\frac{c}{m+3}$ ,  $c$  into  $\frac{b}{m+3}$ , and  $m$  into  $-\frac{m+4}{m+3}$ ; but which is still of Riccati's form. The transformation, it will be observed, is a double one, as it affects the independent as well as the dependent variable.

Now if  $m$  be of the form  $\frac{-4i}{2i-1}$ , we find on substitution and reduction

$$-\frac{m+4}{m+3} = \frac{-4(i-1)}{2(i-1)-1}.$$

Hence, a second double transformation of the same nature as the last will reduce the differential equation to a form in which the index in the second member will become  $-\frac{4(i-2)}{2(i-2)-1}$ . And thus after a series of  $i$  transformations the index is reduced to 0, and the equation becomes solvable by separation of the variables.

To establish another condition of solution, assume in the given equation  $u = \frac{1}{y}$ ,  $x = z^{\frac{1}{m+1}}$ , then, after substitution and reduction, we have

$$\frac{dy}{dz} + \frac{c}{m+1}y^2 = \frac{b}{m+1}z^{-\frac{m}{m+1}},$$

which, by what has preceded, will be solvable if we have

$$-\frac{m}{m+1} = -\frac{4i}{2i-1},$$

$$\text{whence, } m = -\frac{4i}{2i+1}.$$

Combining these results it appears that Riccati's equation is integrable if  $m = \frac{-4i}{2i \pm 1}$ ,  $i$  being 0 or a positive integer. This agrees with (23).

It is manifest from the complexity both of the transformations above described and of the results to which they lead, that Riccati's equation is, in its actual form, far less adapted for such transformations than the equation

$$x \frac{dy}{dx} - ay + by^2 = cx^n,$$

to which it is so easily reduced.

11. Riccati's equation becomes linear on assuming

$$u = \frac{1}{bw} \frac{dw}{dx}.$$

The transformed equation is

$$\frac{d^2w}{dx^2} - bcx^mw = 0 \dots\dots\dots (25).$$

We shall consider it under this form in a subsequent Chapter.  
[See Exercise 3 of Chapter xvii.]

To Riccati's equation some others of greater generality may be reduced by a change of variables, e. g. the equation

$$\frac{du}{dx} + bx^m u^2 = cx^n \dots\dots\dots (26),$$

by assuming  $x^{m+1} = t$ .

### *Euler's Equation.*

It has already appeared that the solution of a differential equation may sometimes be freed from transcendents introduced by integration. An example of this has been afforded in the instance of the equation

$$\frac{dx}{\sqrt{(1-x^2)}} + \frac{dy}{\sqrt{(1-y^2)}} = 0,$$

(Chap. II.), the solution of which is capable of being exhibited in an algebraic form, although immediate integration introduces the transcendental functions  $\sin^{-1}x$ ,  $\sin^{-1}y$ . The inquiry is here suggested whether in any other cases the direct integration may be evaded, an inquiry the more important as our means of integration are so limited. Euler succeeded in obtaining without direct integration the solution of the equation

$$\frac{dx}{\sqrt{(a+bx+cx^2+ex^3+fx^4)}} + \frac{dy}{\sqrt{(a+by+cy^2+ey^3+fy^4)}} = 0,$$

and of some related forms. The result belongs to the theory of the elliptic functions, and may be established independently by the methods which more peculiarly pertain to that theory. But the method by which Euler arrived at that result demands notice here.

12. To integrate the equation

$$\frac{dx}{\sqrt{(a+bx+cx^2+ex^3+fx^4)}} + \frac{dy}{\sqrt{(a+by+cy^2+ey^3+fy^4)}} = 0 \dots\dots(1).$$

Representing the polynomials  $a+bx+cx^2+ex^3+fx^4$ , and

$a + by + cy^2 + ey^3 + fy^4$  by  $X$  and  $Y$  respectively, we have to integrate

$$\frac{dx}{\sqrt{(X)}} + \frac{dy}{\sqrt{(Y)}} = 0 \dots\dots\dots (2).$$

The ordinary *solution* of this equation in the sense of Art. 5, Chap. I. would be

$$\int \frac{dx}{\sqrt{(X)}} + \int \frac{dy}{\sqrt{(Y)}} = C,$$

but it is our present object to obtain an algebraical relation between  $x$  and  $y$  without performing the integrations above implied.

$$\text{Let } \int \frac{dx}{\sqrt{(X)}} = t, \text{ then}$$

$$\frac{dx}{dt} = \sqrt{(X)}, \quad \frac{dy}{dt} = -\sqrt{(Y)} \dots\dots\dots (3).$$

Also let  $x + y = p$ ,  $x - y = q$ . We shall endeavour to form a differential equation in which  $p$  and  $q$  are dependent variables, and  $t$  the independent variable.

From (3) we have

$$\frac{dp}{dt} = \sqrt{(X)} - \sqrt{(Y)} \dots\dots\dots (4),$$

$$\frac{dq}{dt} = \sqrt{(X)} + \sqrt{(Y)} \dots\dots\dots (5),$$

$$\text{therefore } \frac{dp}{dt} \frac{dq}{dt} = X - Y$$

$$= bq + cpq + \frac{1}{4} eq (3p^2 + q^2) + \frac{1}{2} fpq (p^2 + q^2) \dots (6),$$

since the transformations  $x + y = p$ ,  $x - y = q$  give

$$x^2 - y^2 = pq,$$

$$x^3 - y^3 = (x - y) (x^2 + xy + y^2) = q \left( 3p^2 + q^2 \right),$$

$$x^4 - y^4 = (x^2 - y^2)(x^2 + y^2) = pq \left( \frac{p^2 + q^2}{2} \right).$$

Again, from (3) we have

$$\begin{aligned} \frac{d^2x}{dt^2} &= \frac{d\sqrt{X}}{dt} = \frac{dx}{dt} \frac{d\sqrt{X}}{dx} = \frac{1}{2} \frac{dX}{dx}, \\ \frac{d^2y}{dt^2} &= \frac{1}{2} \frac{dY}{dy}; \end{aligned}$$

whence by addition

$$\begin{aligned} \frac{d^2p}{dt^2} &= \frac{1}{2} \left( \frac{dX}{dx} + \frac{dY}{dy} \right) \\ &= b + cp + \frac{3}{4} e (p^2 + q^2) + \frac{1}{2} fp (p^2 + 3q^2) \dots\dots\dots (7), \end{aligned}$$

on effecting the differentiations and transforming as before from  $x$  and  $y$  to  $p$  and  $q$ .

Multiplying (7) by  $q$ , and from the result subtracting (6), we have

$$\begin{aligned} q \frac{d^2p}{dt^2} - \frac{dp}{dt} \frac{dq}{dt} &= \frac{eq^3}{2} + fpq^3 \\ &= \frac{q^3}{2} (e + 2fp). \end{aligned}$$

Therefore

$$\frac{2}{q^2} \frac{d^2p}{dt^2} - \frac{2}{q^3} \frac{dp}{dt} \frac{dq}{dt} = e + 2fp.$$

Now multiplying both sides by  $\frac{dp}{dt}$ ,

$$\frac{2 \frac{dp}{dt} \frac{d^2p}{dt^2}}{q^2} - \left( \frac{dp}{dt} \right)^2 \times \frac{2 \frac{dq}{dt}}{q^3} = (e + 2fp) \frac{dp}{dt} \dots\dots\dots (8),$$

from which, each member being an exact differential, we have on integration

$$\frac{1}{q^2} \left( \frac{dp}{dt} \right)^2 = ep + fp^2 + C,$$

$C$  being an arbitrary constant.

Hence 
$$\frac{dp}{dt} = q\sqrt{(C + ep + fp^2)}.$$

Therefore by (4)

$$\sqrt{(X)} - \sqrt{(Y)} = (x - y) \sqrt{\{C + e(x + y) + f(x + y)^2\}} \dots (9),$$

the integral required.

The student may apply the same process of transformation and reduction to the equation

$$\frac{dx}{\sqrt{(a + bx + cx^2 + ex^3 + fx^4)}} - \frac{dy}{\sqrt{(a + by + cy^2 + ey^3 + fy^4)}} = 0 \dots \dots \dots (10).$$

The resulting integral will be

$$\sqrt{(X)} + \sqrt{(Y)} = (x - y) \sqrt{\{C + e(x + y) + f(x + y)^2\}} \dots (11).$$

13. It will probably appear that there is something arbitrary in the mode in which, in the above investigation, the final differential equation (8) between  $p$ ,  $q$ , and  $t$ , upon which the solution of the problem depends, is formed. The analysis which is subjoined may throw some light upon its real nature, and shew of what general theorem that equation constitutes an expression.

PROP. Whatever may be the form of the function  $\phi(x)$ , the following theorem of development holds good, viz.

$$\begin{aligned} \phi(y) - \phi(x) &= A_1 \{\phi'(y) + \phi'(x)\} (y - x) \\ &+ A_3 \{\phi'''(y) + \phi'''(x)\} (y - x)^3 \\ &+ A_5 \{\phi^{(5)}(y) + \phi^{(5)}(x)\} (y - x)^5 + \&c. \dots (12), \end{aligned}$$

wherein  $A_1$ ,  $A_3$ ,  $A_5$ , &c. are the coefficients of the successive powers of  $x$ , in the development of the function  $\frac{e^x - 1}{e^x + 1}$  in a series of the form

$$A_1 x + A_3 x^3 + A_5 x^5 + \&c.$$

For let  $y = x + h$ , then, employing a well-known symbolical form of Taylor's theorem,

$$\begin{aligned}
 \phi(y) - \phi(x) &= \phi(x + h) - \phi(x) \\
 &= (\epsilon^{h \frac{d}{dx}} - 1) \phi(x) \\
 &= \frac{\epsilon^{h \frac{d}{dx}} - 1}{\epsilon^{h \frac{d}{dx}} + 1} (\epsilon^{h \frac{d}{dx}} + 1) \phi(x) \\
 &= \frac{\epsilon^{h \frac{d}{dx}} - 1}{\epsilon^{h \frac{d}{dx}} + 1} \left\{ \phi(x + h) + \phi(x) \right\} \\
 &= \left\{ A_1 h \frac{d}{dx} + A_3 h^3 \left( \frac{d}{dx} \right)^3 + \&c. \right\} \left\{ \phi(x + h) + \phi(x) \right\} \\
 &\dots\dots\dots(13),
 \end{aligned}$$

where  $A_1, A_3, \&c.$  have the series of values above described. Hence, performing the differentiations and replacing  $x + h$  by  $y$ , and  $h$  by  $y - x$ , we have

$$\begin{aligned}
 \phi(y) - \phi(x) &= A_1 \{ \phi'(y) + \phi'(x) \} (y - x) \\
 &\quad + A_3 \{ \phi'''(y) + \phi'''(x) \} (y - x)^3 + \&c....(14),
 \end{aligned}$$

which is the proposition in question.

The values of  $A_1, A_3, A_5, \&c.$  may be expressed by means of Bernoulli's numbers, but they may also be calculated very simply by developing the exponentials in the fraction  $\frac{\epsilon^x - 1}{\epsilon^x + 1}$ , and then expanding the fraction itself by division. We readily find

$$A_1 = \frac{1}{2}, \quad A_3 = -\frac{1}{24}, \quad A_5 = \frac{1}{240}, \quad A_7 = -\frac{17}{40320}, \quad \&c.$$

When  $\phi(x)$  is a polynomial of the fourth degree, we have

$$\phi^v(x) = 0, \quad \phi^vi(x) = 0, \quad \&c.,$$

and the theorem is reduced to the following, viz.:

$$\begin{aligned}\phi(y) - \phi(x) &= \frac{1}{2} \{\phi'(y) + \phi'(x)\} (y - x) \\ &\quad - \frac{1}{24} \{\phi'''(y) + \phi'''(x)\} (y - x)^3 \dots\dots (15).\end{aligned}$$

Now the differential equation (8) into whose origin we are inquiring is merely a transformation of the last theorem. We will on this occasion, and for the sake of variety, exemplify the above remark in the solution of the differential equation

$$\frac{dx}{\sqrt{\{\phi(x)\}}} = \frac{dy}{\sqrt{\{\phi(y)\}}} \dots\dots\dots (16),$$

in which

$$\phi(x) = a + bx + cx^2 + ex^3 + fx^4 \dots\dots\dots (17),$$

$$\phi(y) = a + by + cy^2 + ey^3 + fy^4 \dots\dots\dots (18).$$

Representing either member of (16) by  $dt$  and assuming  $t$  as an independent variable, substitute the values hence determined for  $\phi(x)$ ,  $\phi'(x)$ ,  $\phi'''(x)$ , &c. in the theorem (15). There will result

$$\frac{dx}{dt} = \sqrt{\{\phi(x)\}}, \quad \frac{dy}{dt} = \sqrt{\{\phi(y)\}}.$$

Hence 
$$\phi(x) = \left(\frac{dx}{dt}\right)^2, \quad \phi(y) = \left(\frac{dy}{dt}\right)^2,$$

$$\begin{aligned}\phi'(x) &= \frac{d}{dx} \left(\frac{dx}{dt}\right)^2 = \frac{dt}{dx} \frac{d}{dt} \left(\frac{dx}{dt}\right)^2 \\ &= 2 \frac{d^2x}{dt^2},\end{aligned}$$

$$\phi'(y) = 2 \frac{d^2y}{dt^2}.$$

Lastly from (17) and (18)

$$\phi'''(x) = 24fx + 6e,$$

$$\phi'''(y) = 24fy + 6e,$$

by which substitution, (15) becomes

$$\left(\frac{dy}{dt}\right)^2 - \left(\frac{dx}{dt}\right)^2 = \left(\frac{d^2y}{dt^2} + \frac{d^2x}{dt^2}\right)(y-x) - \left(fx + fy + \frac{e}{2}\right)(y-x)^3.$$

Or, transposing

$$\left(\frac{dy}{dt}\right)^2 - \left(\frac{dx}{dt}\right)^2 + (x-y)\left(\frac{d^2x}{dt^2} + \frac{d^2y}{dt^2}\right) = \left(fx + fy + \frac{e}{2}\right)(y-x)^3 \dots (19).$$

Now the very *form* of this equation suggests the transformation  $x + y = p$ ,  $x - y = q$ , by which it becomes

$$-\frac{dp}{dt} \frac{dq}{dt} + q \frac{d^2p}{dt^2} = \left(fp + \frac{e}{2}\right) q^3,$$

whence multiplying by  $\frac{2}{q^3} dp$  and integrating

$$\left(\frac{dp}{dt}\right)^2 \div q^2 = fp^2 + ep + C;$$

therefore

$$\left[\frac{\sqrt{\{\phi(x)\}} + \sqrt{\{\phi(y)\}}}{x-y}\right]^2 = f(x+y)^2 + e(x+y) + C \dots (20),$$

the integral sought.

## EXERCISES.

$$1. \quad x \frac{dy}{dx} - ay + y^2 = x^{-2a}.$$

$$2. \quad x \frac{dy}{dx} - ay + y^2 = x^{-\frac{2a}{3}}.$$

$$3. \quad \frac{du}{dx} + u^2 = cx^{-\frac{4}{3}}.$$

$$4. \quad \frac{du}{dx} + bu^2 = cx^{-4}.$$

5.  $\frac{du}{dx} - u^2 = 2x^{-\frac{2}{3}}.$

6. Assuming the conditions for the solution of Riccati's equation, Art. 9, investigate those under which the equation  $\frac{du}{dx} + bx^m u^2 = cx^n$  is integrable.

7. Assuming the conditions, Art. 6, under which

$$x \frac{dy}{dx} - ay + by^2 = cx^n$$

is integrable in finite terms, investigate those under which the equation

$$x \frac{dy}{dx} + \alpha + \beta y + \gamma y^2 = \delta x^n$$

is integrable in finite terms.

8. Transforming the equation  $x \frac{dy}{dx} - ay + by^2 = cx^{2a}$ , by assuming  $x^a = t$ , an integrating factor may be found by Art. 6, Chap. v.

9. The equation  $\frac{du}{dx} + bu^2 = cx^m + \frac{h}{x^2}$ , more general than Riccati's, is reducible to the form  $x \frac{dy}{dx} - a'y + b'y^2 = c'x^n$ , considered in Art. 3, by an assumption of the form  $u = \frac{y - A}{x}$ .

10. Hence investigate the conditions under which the former equation may be solved.

11. The same equation may be reduced to Riccati's form by an assumption of the form  $y = Ax^{-1} + z\phi(x)$ , followed by a transformation affecting only  $x$ .

12. Integrate the equation

$$\frac{dx}{\sqrt{(a+bx+cx^2+ex^3+fx^4)}} + \frac{dy}{\sqrt{(a+by+cy^2+ey^3+fy^4)}} = 0,$$

by the application of the theorem of Art. 13.

13. Deduce from that theorem the following expression for the value of a definite integral, viz.:

$$\begin{aligned} \int_a^b \phi(x) dx = & \frac{\phi(a) + \phi(b)}{2} (b-a) - \frac{\phi''(a) + \phi''(b)}{24} (b-a)^3 \\ & + \frac{\phi^{iv}(a) + \phi^{iv}(b)}{240} (b-a)^5 - \&c. \end{aligned}$$

## CHAPTER VII.

### ON DIFFERENTIAL EQUATIONS OF THE FIRST ORDER, BUT NOT OF THE FIRST DEGREE.

1. REFERRING to the general type of differential equations of the first order, viz.:

$$F\left(x, y, \frac{dy}{dx}\right) = 0,$$

we have now to consider those cases in which  $\frac{dy}{dx}$  is so involved that the given equation cannot be reduced to the form

$$M + N \frac{dy}{dx} = 0,$$

already considered.

Freed from radicals the supposed equation will, however, present itself in the form

$$\left(\frac{dy}{dx}\right)^n + P_1 \left(\frac{dy}{dx}\right)^{n-1} + P_2 \left(\frac{dy}{dx}\right)^{n-2} + \dots + P_n = 0 \dots\dots (1),$$

where  $P_1, P_2, \dots P_n$  are functions of  $x$  and  $y$ .

An obvious preparation for the solution of such an equation, is to resolve its first member, considered as algebraic with respect to the differential coefficient  $\frac{dy}{dx}$ , into its component factors of the first degree. If  $p_1, p_2 \dots p_n$  be the roots of (1) thus considered, we shall have

$$\left(\frac{dy}{dx} - p_1\right) \left(\frac{dy}{dx} - p_2\right) \dots \left(\frac{dy}{dx} - p_n\right) = 0 \dots\dots\dots (2),$$

$p_1, p_2, \dots p_n$  being supposed to be determined as known functions of  $x$  and  $y$ . And it is now manifest that any relation between  $x$  and  $y$  which makes either one or more than one of the factors of the first member to vanish, will be a solution of the equation, and that no relation between  $x$  and  $y$  not possessing this character will be such. Hence if we solve the separate equations

$$\frac{dy}{dx} - p_1 = 0, \quad \frac{dy}{dx} - p_2 = 0, \quad \dots \quad \frac{dy}{dx} - p_n = 0 \dots\dots\dots (3),$$

any one of the solutions obtained will be a solution of (2), since it will make one of its factors to vanish. And if we express the different solutions thus obtained, each with its arbitrary constant annexed, in the forms

$$V_1 - C_1 = 0, \quad V_2 - C_2 = 0, \quad \dots \quad V_n - C_n = 0,$$

any product of two or more of these equations will also be a solution of (2), since it will cause two or more of its factors to vanish.

Ex. Given the differential equation

$$\left(\frac{dy}{dx}\right)^2 - a^2 y^2 = 0 \dots\dots\dots (4).$$

Here the component equations are

$$\frac{dy}{dx} - ay = 0,$$

$$\frac{dy}{dx} + ay = 0,$$

and their respective solutions are

$$\log y - ax - c_1 = 0 \dots\dots\dots (5),$$

$$\log y + ax - c_2 = 0 \dots\dots\dots (6).$$

Either of these equations is a solution of the given equation, and so is their product

$$(\log y - ax - c_1)(\log y + ax - c_2) = 0 \dots\dots\dots (7).$$

2. And here two important questions are suggested. First, how is it that two arbitrary constants present themselves in the solution of an equation of the first order? Secondly, is it possible to express with equal generality the solution of the equation by a primitive containing a *single* arbitrary constant in accordance with what has been said of the genesis of differential equations of the first order, Chap. I. Art. 6? These are connected questions, and they will be answered together.

The equation (7) implies that  $y$  admits of two values each involving an arbitrary constant, but it does not imply that  $y$  admits of a value involving two arbitrary constants. The component factors of the solution separately equated to 0, as in (5) and (6), give respectively

$$y = C_1 \epsilon^{ax}, \quad y = C_2 \epsilon^{-ax} \dots\dots\dots(8),$$

each of which involves one arbitrary constant only, and each of which corresponds to a single factor of the given differential equation. The true canon is, not that a general solution of an equation of the first order can involve only one arbitrary constant in its expression, but that *each value of  $y$*  which such a solution establishes involves in its expression only a single arbitrary constant.

At the same time there is a real sense in which it remains true that every differential equation of the first order, whatever its degree may be, implies the existence of a complete primitive involving a single arbitrary constant, and there is a real sense in which such primitive constitutes the general solution of the differential equation. To reconcile these seeming contradictions I shall shew that if we suppose the arbitrary constants  $c_1$  and  $c_2$  in (7) identical, and accordingly replace each of them by  $c$ , we shall have an equation which will be, first the true primitive of (4), in that it will generate that equation by differentiation and the elimination of  $c$ , secondly its general solution, in that no particular relation is deducible from the solution (7) involving two arbitrary constants which may not also, by the use of a lawful freedom of interpretation, be derived from it.

Thus replacing  $c_1$  and  $c_2$  by  $c$ , we have

$$(\log y - ax - c)(\log y + ax - c) = 0 \dots\dots\dots(9),$$

$$\text{whence } (\log y)^2 - a^2x^2 - 2c \log y + c^2 = 0.$$

Differentiating, and representing  $\frac{dy}{dx}$  by  $p$ ,

$$2 \log y \frac{p}{y} - 2a^2x - 2c \frac{p}{y} = 0,$$

$$\text{whence } c = -\frac{a^2xy}{p} + \log y.$$

Substituting this value in (9), we have

$$\left(\frac{a^2xy}{p} - ax\right)\left(\frac{a^2xy}{p} + ax\right) = 0,$$

which reduces to

$$a^2x^2 (a^2y^2 - p^2) = 0.$$

Or, rejecting the factor  $a^2x^2$  which does not contain  $p$ , and replacing  $p$  by  $\frac{dy}{dx}$ ,

$$\left(\frac{dy}{dx}\right)^2 - a^2y^2 = 0,$$

the differential equation given. Thus (9) is its complete primitive.

Again, that solution is *general*. The two relations between  $y$  and  $x$  which it furnishes are

$$y = C\epsilon^{ax}, y = C\epsilon^{-ax} \dots\dots\dots(10),$$

and these differ in expression from (8) only in that the arbitrary constant is here supposed to be the same in one as in the other, but as it is arbitrary and admits of any value, there is no single relation implied in (8) which is not also implied in (10). And it is *in this sense* that the generality of the solution is affirmed.

[See the *Supplementary Volume*, Chapter xx. Art. 1.]

3. These illustrations will prepare the way for the demonstration of the general theorem which they exemplify.

**THEOREM.** *If the differential equation of the first order and  $n^{\text{th}}$  degree be resolved into its component equations*

$$\frac{dy}{dx} - p_1 = 0, \quad \frac{dy}{dx} - p_2 = 0, \dots \frac{dy}{dx} - p_n = 0,$$

*and if the complete primitives of these equations are  $V_1 = c_1$ ,  $V_2 = c_2$ , ...  $V_n = c_n$ , then the complete primitive of the given equation will be*

$$(V_1 - c)(V_2 - c) \dots (V_n - c) = 0.$$

Let us first examine the case in which the proposed differential equation is of the second degree, and therefore expressible in the form  $\left(\frac{dy}{dx} - p_1\right)\left(\frac{dy}{dx} - p_2\right) = 0$ . Suppose that the integral  $V_1 = c_1$  is derived from the equation  $\frac{dy}{dx} - p_1 = 0$  by means of an integrating factor  $\mu_1$ . Then  $dV_1 = \mu_1 \left(\frac{dy}{dx} - p_1\right) dx$ . In like manner we shall have  $dV_2 = \mu_2 \left(\frac{dy}{dx} - p_2\right) dx$ . Now taking the equation

$$(V_1 - c)(V_2 - c) = 0 \dots \dots \dots (11)$$

as a primitive, we have, on differentiating with respect to  $x$  and  $y$ ,

$$(V_1 - c) dV_2 + (V_2 - c) dV_1 = 0 \dots \dots \dots (12).$$

Therefore 
$$c = \frac{V_1 dV_2 + V_2 dV_1}{dV_1 + dV_2},$$

whence 
$$V_1 - c = \frac{(V_1 - V_2) dV_1}{dV_1 + dV_2},$$

$$V_2 - c = \frac{(V_2 - V_1) dV_2}{dV_1 + dV_2}.$$

Substituting these values in (11), we have

$$(V_1 - V_2)^2 dV_1 dV_2 = 0 \dots\dots\dots(13),$$

which gives  $(V_1 - V_2)^2 \mu_1 \mu_2 \left( \frac{dy}{dx} - p_1 \right) \left( \frac{dy}{dx} - p_2 \right) = 0 \dots (14).$

And this, on rejecting the factor  $(V_1 - V_2)^2 \mu_1 \mu_2$  which does not contain any differential coefficients, becomes identical with the given differential equation. Hence  $(V_1 - c)(V_2 - c) = 0$  is the complete primitive of that equation.

To generalize this particular demonstration it would be necessary to eliminate  $c$  between the equation

$$(V_1 - c)(V_2 - c) \dots (V_n - c) = 0 \dots\dots\dots(15),$$

and the equation thence derived by differentiation with respect to  $x$  and  $y$ . The ordinary process of elimination, as exemplified above in the particular case in which  $n = 2$ , would be complex, but the result may be determined without difficulty by logical considerations. It will suffice for this purpose to consider the case in which  $n = 3$ .

We have then as the supposed primitive

$$(V_1 - c)(V_2 - c)(V_3 - c) = 0 \dots\dots\dots(16),$$

and as the derived equation

$$\begin{aligned} & (V_2 - c)(V_3 - c) \left( \frac{dV_1}{dx} + \frac{dV_1}{dy} \frac{dy}{dx} \right) \\ & + (V_3 - c)(V_1 - c) \left( \frac{dV_2}{dx} + \frac{dV_2}{dy} \frac{dy}{dx} \right) \\ & + (V_1 - c)(V_2 - c) \left( \frac{dV_3}{dx} + \frac{dV_3}{dy} \frac{dy}{dx} \right) = 0 \dots\dots(17). \end{aligned}$$

Now (16) implies that some one at least of the equations

$$V_1 - c = 0, \quad V_2 - c = 0, \quad V_3 - c = 0,$$

is satisfied.

If the first of these equations is satisfied we have  $c = V_1$ , and substituting this value in (17) there results

$$(V_2 - V_1)(V_3 - V_1)dV_1 = 0 \dots \dots \dots (18).$$

If the second equation of the system is satisfied we have in like manner

$$(V_3 - V_2)(V_1 - V_2)dV_2 = 0 \dots \dots \dots (19).$$

If the third equation of the system is satisfied we have

$$(V_1 - V_3)(V_2 - V_3)dV_3 = 0 \dots \dots \dots (20).$$

Hence the existence of (16) as primitive supposes the existence of some one at least of the equations (18), (19), (20), and therefore of the equation

$$(V_2 - V_3)^2(V_3 - V_1)^2(V_1 - V_2)^2dV_1dV_2dV_3 = 0 \dots \dots (21),$$

which is formed by multiplying those equations together.

Conversely the supposition that the equation (21) is true, involves the supposition that one at least of the equations (18), (19), (20) is true.

The equation (21) is therefore *equivalent* to the result which ordinary elimination applied to (16) and (17) would give. The same process of reasoning applied to the more general equation (15) as supposed primitive, would lead to a result of the form

$$KdV_1dV_2\dots dV_n = 0 \dots \dots \dots (22),$$

$K$  being the product of the squares of the differences of  $V_1, V_2, \dots V_n$ .

On comparison with (13) we see that in the particular case of  $n = 2$ , this is not only equivalent to but identical with the result of ordinary elimination in that case. And this identity of form, though it is not necessary to our present purpose to establish it, might be demonstrated generally.

$$\text{Now } dV_1 = \mu_1 \left( \frac{dy}{dx} - p_1 \right) dx, \quad dV_2 = \mu_2 \left( \frac{dy}{dx} - p_2 \right) dx, \quad \&c.$$

Hence (22) gives

$$K\mu_1\mu_2\dots\mu_n\left(\frac{dy}{dx}-p_1\right)\left(\frac{dy}{dx}-p_2\right)\dots\left(\frac{dy}{dx}-p_n\right)=0,$$

or, rejecting the factor  $K\mu_1\mu_2\dots\mu_n$ , which does not contain differential coefficients,

$$\left(\frac{dy}{dx}-p_1\right)\left(\frac{dy}{dx}-p_2\right)\dots\left(\frac{dy}{dx}-p_n\right)=0.$$

Of this equation it has therefore been shewn, as was required, that  $(V_1-c)(V_2-c)\dots(V_n-c)=0$  constitutes the complete primitive.

[See the *Supplementary Volume*, Chapter xx. Art. 2.]

Ex. Given  $\left(\frac{dy}{dx}\right)^2 - \frac{a}{x} = 0$  .....(1).

Here the component equations are

$$\frac{dy}{dx} - \left(\frac{a}{x}\right)^{\frac{1}{2}} = 0, \quad \frac{dy}{dx} + \left(\frac{a}{x}\right)^{\frac{1}{2}} = 0,$$

and their respective integrals are

$$y - c_1 - 2\sqrt{ax} = 0 \dots\dots\dots(2),$$

$$y - c_2 + 2\sqrt{ax} = 0 \dots\dots\dots(3).$$

Replacing both constants by  $c$  and multiplying the equations together, we have

$$(y - c)^2 - 4ax = 0 \dots\dots\dots(4),$$

as the complete primitive.

Now this primitive represents a series of parabolas, the parameters of which are constant and equal to  $4a$ , and the axes of which are parallel to the axis of  $x$ ; but the vertices of which are situated at different points of the axis of  $y$ , corresponding to the different values which may be given to the arbitrary constant  $c$ . Of these parabolas the equations (2) and (3), which may be written in the more usual forms

$$y - c_1 = 2\sqrt{ax}, \quad y - c_2 = -2\sqrt{ax},$$

represent respectively the positive and the negative branches, while the equation

$$\{y - c_1 - 2\sqrt{ax}\} \{y - c_2 + 2\sqrt{ax}\} = 0 \dots\dots\dots (5),$$

represents the terms which would be found by taking one positive and one negative branch, *but not necessarily from the same parabola*. Thus there is no portion of the loci represented by the apparently more general solution (5), which is not also represented by the complete primitive (4). The defect of generality, if as such it is to be regarded, consists in this that while each branch of every curve in the series is represented, those branches which belong to the same curve are paired together.

[On the subject discussed in the first three Articles of the present Chapter the student may consult a paper by Professor De Morgan entitled *On the question, What is the solution of a Differential Equation?* The paper is published in the *Cambridge Philosophical Transactions*, Vol. x.]

4. There are certain cases in which differential equations of the first order can be solved without the resolution of the first member into its component factors. Of these the most important are the following.

1st. When the given equation contains only one of the variables  $x$  and  $y$  in addition to  $\frac{dy}{dx}$ , being either of the form

$$F\left(x, \frac{dy}{dx}\right) = 0, \text{ or of the form } F\left(y, \frac{dy}{dx}\right) = 0.$$

2ndly. When, involving  $x$  and  $y$  only in the first degree, it is expressible in the form

$$x\phi(p) + y\psi(p) = \chi(p), \text{ where } p = \frac{dy}{dx}.$$

3rdly. When the equation is homogeneous with respect to  $x$  and  $y$ .

These cases we shall consider separately.

*Equations involving only one of the variables  $x$  and  $y$   
with  $\frac{dy}{dx}$ .*

5. In this case if, representing  $\frac{dy}{dx}$  by  $p$ , and regarding  $p$  as a new variable, we form a differential equation between  $p$  and the variable which does not enter into the original equation, and integrate the equation thus formed, the elimination of  $p$  between the resulting integral and the original equation will give the complete primitive required. For it will express a relation between  $x$ ,  $y$ , and the arbitrary constant introduced by integration.

Thus if from the equation  $F(x, p) = 0$  we deduce  $x = f(p)$ , then, since  $dy = p dx$ , we have

$$dy = p f'(p) dp;$$

therefore 
$$y = \int p f'(p) dp + c \dots\dots\dots (1).$$

After the integration here implied  $y$  will be expressed as a function of  $p$  and  $c$ , and between that result and the original equation  $p$  must be eliminated.

In like manner, if from  $F(y, p) = 0$  we deduce  $y = f(p)$ , the equation  $dy = p dx$  gives  $f'(p) dp = p dx$ , whence

$$dx = \frac{f'(p)}{p} dp,$$

whence

$$x = \int \frac{f'(p)}{p} dp + c \dots\dots\dots (2),$$

between which (after the integration has been performed) and the original equation,  $p$  must be eliminated.

But these methods, though always permissible, are only advantageous when it is more easy to solve the given equation, with respect to the variable  $x$  or  $y$  which it involves, than with respect to  $p$ .

Ex. 1. Given  $x = 1 + p^3$ .

$$\text{Here } dy = p dx = p \times 3p^2 dp = 3p^3 dp ;$$

therefore 
$$y = \frac{3p^4}{4} + c \dots\dots\dots (3).$$

Now as the original equation gives  $p = (x - 1)^{\frac{1}{3}}$ , the complete primitive found by substitution of this value in (3) will be

$$y = \frac{3}{4} (x - 1)^{\frac{4}{3}} + c \dots\dots\dots (4),$$

and it would be directly obtained in this form by integrating the original equation reduced by algebraic solution to the form

$$\frac{dy}{dx} = (x - 1)^{\frac{1}{3}}.$$

This example illustrates the process but not its advantages.

Ex. 2. Given  $x = 1 + p + p^3$ .

$$\text{Here } dy = p dx = p dp + 3p^3 dp ;$$

therefore 
$$y = \frac{p^2}{2} + \frac{3p^4}{4} + c \dots\dots\dots (5),$$

between which and the original equation  $p$  must be eliminated. We may do this so as to obtain the final equation between  $x$  and  $y$  in a rational form; but, if this object is not deemed important, we may, by the solution of a quadratic, determine  $p$  from (5) and substitute its value in the given equation.

Ex. 3. Given  $y = p^2 + 2p^3$ .

$$\text{Here since } p dx = dy \text{ we have}$$

$$dx = \frac{1}{p} dy = 2dp + 6p dp ;$$

therefore 
$$x = 2p + 3p^2 + c.$$

From this equation we find

$$p = \frac{-1 \pm \sqrt{(3x + C)}}{3},$$

$C$  being an arbitrary constant introduced in the place of  $1 - 3c$ ; and  $y$  will be found by substituting this value of  $p$  in the original equation.

*Equations in which  $x$  and  $y$  are involved only in the first degree, the typical form being  $x\phi(p) + y\psi(p) = \chi(p)$ .*

6. Any equation of the above class may be reduced to a linear differential equation between  $x$  and  $p$ , after the solution of which,  $p$  must be eliminated.

The reduced equation is found by differentiating the given equation and then eliminating, if necessary, the variable  $y$ . It may happen that such elimination is unnecessary,  $y$  disappearing through differentiation.

Ex. Let us apply this method to the equation

$$y = xp + f(p) \dots \dots \dots (1),$$

usually termed Clairaut's equation.

Differentiating, we have

$$p = p + x \frac{dp}{dx} + f'(p) \frac{dp}{dx},$$

whence  $\{x + f'(p)\} \frac{dp}{dx} = 0.$

Now this is resolvable into the two equations,

$$x + f'(p) = 0 \dots \dots \dots (2),$$

$$\frac{dp}{dx} = 0 \dots \dots \dots (3).$$

The second of these, which alone contains differentials of the new variables  $x$  and  $p$ , is the true *differential* equation between  $x$  and  $p$ .

Integrating it we have  $p = c$ ,  
and substituting this value of  $p$  in (1),

$$y = cx + f(c) \dots\dots\dots (4),$$

which is the complete primitive required.

But what relation does the rejected equation (2) bear to the given differential equation (1), and what relation to its complete primitive just obtained?

If we eliminate  $p$  between (1) and (2) we obtain a new relation between  $x$  and  $y$  not included in the complete primitive already found, i. e. not deducible from that primitive by assigning a particular value to its arbitrary constant, and yet satisfying the same differential equation, and, as we shall hereafter see, connected in a remarkable manner with the complete primitive. Such a relation between  $x$  and  $y$  is called a singular solution. We shall enter more fully into the theory of singular solutions in a distinct Chapter, but the following example will throw some light upon their nature, as well as illustrate the process above described.

Ex. Given  $y = xp + \frac{m}{p}$ .

Here differentiating we have

$$0 = \left(x - \frac{m}{p^2}\right) \frac{dp}{dx}.$$

From the equation  $\frac{dp}{dx} = 0$ , we have  $p = c$ , whence

$$y = cx + \frac{m}{c} \dots\dots\dots (5),$$

the complete primitive. From the equation  $x - \frac{m}{p^2} = 0$ , we have

$$p = \sqrt{\left(\frac{m}{x}\right)},$$

and this value substituted in the original equation gives, after freeing the result from radical signs,

$$y^2 = 4mx \dots\dots\dots(6),$$

the singular solution.

Here the singular solution (6) is the equation of a parabola whose parameter is  $4m$ , and the complete primitive (5) is the well-known equation of that tangent to the same parabola which makes with the axis of  $x$  an angle whose trigonometrical tangent is  $c$ .

Now, for the infinitesimal element in which the curve and its tangent coincide, the values of  $x$ ,  $y$ , and  $\frac{dy}{dx}$  are the same in both. And thus it is that the algebraic equations of the curve and of its tangent satisfy the same differential equation of the first order.

On the other hand, if (5) be regarded as the general equation of a system of straight lines, each straight line in that system being determined by giving a special value to  $c$  in the equation, the envelop or boundary curve of the system will be determined by (6). Here the singular solution is presented as the equation of the envelop of the system of lines defined by the complete primitive.

7. In the second place let us consider the more general equation

$$y = xf(p) + \phi(p).$$

Differentiating, we have

$$p = f(p) + \left\{ xf'(p) + \phi'(p) \right\} \frac{dp}{dx},$$

whence 
$$\left\{ p - f(p) \right\} \frac{dx}{dp} - f'(p) x = \phi'(p),$$

or 
$$\frac{dx}{dp} - \frac{f'(p)}{p - f(p)} x = \frac{\phi'(p)}{p - f(p)},$$

a linear equation of the first order by which  $x$  may be determined as a function of  $p$ . The elimination of  $p$  between the resulting equation and the given one will give the complete primitive.

The typical equation

$$x\phi(p) + y\psi(p) = \chi(p)$$

may be reduced to the above form by dividing by  $\psi(p)$ , but it may also be treated independently by direct differentiation.

Instead however of forming a differential equation between  $x$  and  $p$ , we may form a differential equation between  $y$  and  $p$ . Or, with greater generality, representing any proposed function of  $p$  by  $t$ , we may form a differential equation between either of the primitive variables and  $t$ . Such a differential equation will necessarily be linear with respect to the primitive variable retained, and its solution must of course be followed by the elimination of  $t$ . And this general procedure, more fully to be exemplified when we come to treat of some of the inverse problems of Geometry and of Optics, is often attended with signal advantage.

Ex. Given  $x + yp = ap^2$ .

We shall reduce this to a differential equation between  $x$  and  $p$ .

Differentiating, we have

$$1 + p^2 + y \frac{dp}{dx} = 2ap \frac{dp}{dx},$$

then eliminating  $y$  by means of the given equation, we have

$$1 + p^2 + \left( \frac{ap^2 - x}{p} \right) \frac{dp}{dx} = 2ap \frac{dp}{dx},$$

which may be reduced to the linear form

$$\frac{dx}{dp} - \frac{x}{p(1+p^2)} = \frac{ap}{1+p^2},$$

its integral being

$$x = \frac{p}{\sqrt{1+p^2}} [C + a \log \{p + \sqrt{1+p^2}\}].$$

If in this equation we substitute for  $p$  its value in terms of  $x$  and  $y$  furnished by the given equation, i.e. if we make

$$p = \frac{y \pm \sqrt{(y^2 + 4ax)}}{2a},$$

we shall be in possession of the complete primitive.

Had we chosen to form a differential equation between  $y$  and  $p$ , we should have, on differentiating the given equation while regarding  $y$  as the independent variable,

$$\frac{dx}{dy} + p + y \frac{dp}{dy} = 2ap \frac{dp}{dy},$$

whence, replacing  $\frac{dx}{dy}$  by  $\frac{1}{p}$  and reducing,

$$\frac{dy}{dp} + \frac{p}{1+p^2} y = \frac{2ap^2}{1+p^2},$$

therefore on integration

$$y = \frac{1}{\sqrt{(1+p^2)}} [C + ap \sqrt{(1+p^2)} - a \log \{p + \sqrt{(1+p^2)}\}],$$

from which, as before,  $p$  must be eliminated. The final results are of course identical.

### *Homogeneous Equations of the first order.*

8. Equations which are homogeneous with respect to  $x$  and  $y$  may be prepared for solution by assuming  $y = vx$ .

The typical form of such equations is

$$x^n \phi \left( \frac{y}{x}, p \right) = 0 \dots \dots \dots (1).$$

Assuming then  $\frac{y}{x} = v$ , and dividing by  $x^n$ , we have

$$\phi(v, p) = 0 \dots \dots \dots (2).$$

If we can solve this equation with respect to  $p$ , we have

$$p = f(v).$$

But, since  $y = xv$ ,

$$p = x \frac{dv}{dx} + v.$$

Thus the transformed equation becomes

$$x \frac{dv}{dx} + v = f(v),$$

whence

$$\frac{dv}{v - f(v)} + \frac{dx}{x} = 0,$$

an equation in which the variables are separated, and in the integral of which it will only remain to substitute for  $v$  its value  $\frac{y}{x}$ .

But if it be more easy to solve (2) with respect to  $v$  than with respect to  $p$ , and if the result be

$$v = f(p),$$

then restoring to  $v$  its value  $\frac{y}{x}$ , we have

$$y = xf(p),$$

which is a particular case of the equation of the previous section. Hence differentiating, we have

$$p = f(p) + xf'(p) \frac{dp}{dx},$$

from which results

$$\frac{dx}{x} + \frac{f'(p) dp}{f(p) - p} = 0,$$

an equation in which the variables  $x$  and  $p$  are separated. Between the integral of this equation and the given equation  $p$  must be eliminated, and the relation between  $x$  and  $y$  which results will be the complete primitive.

Ex. Given  $yp + nx = \sqrt{(y^2 + nx^2)} \sqrt{(1 + p^2)}$ .

Assuming  $y = vx$ , we have

$$vp + n = \sqrt{(v^2 + n)} \sqrt{(1 + p^2)},$$

the solution of which with respect to  $p$  gives

$$p = v \pm \sqrt{\left(\frac{n-1}{n}\right)} \sqrt{(v^2 + n)}.$$

But  $p = x \frac{dv}{dx} + v$ .

Therefore  $x \frac{dv}{dx} = \pm \sqrt{\left(\frac{n-1}{n}\right)} \sqrt{(v^2 + n)},$

$$\frac{dv}{\sqrt{(v^2 + n)}} = \pm \sqrt{\left(\frac{n-1}{n}\right)} \frac{dx}{x}.$$

Integrating, we have

$$\log \{v + \sqrt{(v^2 + n)}\} = \pm \sqrt{\left(\frac{n-1}{n}\right)} \log x + C;$$

therefore  $v + \sqrt{(v^2 + n)} = cx^{\pm \sqrt{\left(\frac{n-1}{n}\right)}}$ ,

or, replacing  $v$  by  $\frac{y}{x}$ ,

$$y + \sqrt{(y^2 + nx^2)} = cx^{1 \pm \sqrt{\left(\frac{n-1}{n}\right)}}$$

the complete primitive.

*Equations solvable by differentiation.*

9. A remarkable class of equations, the theory of which has been fully discussed by Lagrange, deserves attention.

It has been shewn, Chap. I. Art. 9, that if two differential equations of the first order, each involving a distinct arbitrary constant, give rise to the same differential equation of the second order, they are derived from a common primitive involving both the arbitrary constants in question.

Let us suppose these differential equations of the first order to be reduced to the forms

$$\phi \left( x, y, \frac{dy}{dx} \right) = a \dots\dots\dots(1),$$

$$\psi \left( x, y, \frac{dy}{dx} \right) = b \dots\dots\dots(2),$$

and let the primitive obtained by the elimination of  $\frac{dy}{dx}$  be  $\Phi(x, y, a, b) = 0$ . Lagrange has then observed that if we have any differential equation of the first order of the form

$$F \left\{ \phi \left( x, y, \frac{dy}{dx} \right), \psi \left( x, y, \frac{dy}{dx} \right) \right\} = 0 \dots\dots(3),$$

its complete primitive will still be  $\Phi(x, y, a, b) = 0$ , but with the condition that  $a$  and  $b$  are no longer independent constants, but are connected by the relation

$$F(a, b) = 0.$$

This is an obvious truth. For as, by hypothesis, the supposed primitive  $\Phi(x, y, a, b) = 0$  gives

$$\phi \left( x, y, \frac{dy}{dx} \right) = a, \quad \psi \left( x, y, \frac{dy}{dx} \right) = b,$$

it will convert (3) into  $F(a, b) = 0$ , and will therefore *satisfy* that equation if  $a$  and  $b$  are connected by the relation

$$F(a, b) = 0.$$

Moreover it contains virtually only one arbitrary constant, for the relation  $F(a, b) = 0$  permits us to determine  $b$  as a function of  $a$ . Hence it will constitute the complete primitive of (3). See also Chap. I. Art. 10.

This result may be expressed in the following theorem.

*If any differential equation of the first order be expressible in the form*

$$F(\phi, \psi) = 0 \dots\dots\dots (4),$$

*where  $\phi$  and  $\psi$  are functions of  $x, y, \frac{dy}{dx}$ , such that the differential equations*

$$\phi = a, \quad \psi = b,$$

*are derivable from a single primitive involving  $a$  and  $b$  as arbitrary constants, the solution of the given differential equation will be found by limiting that primitive by the condition*

$$F(a, b) = 0,$$

*so as actually or virtually to eliminate one of the arbitrary constants.*

Ex. Suppose that the given equation is

$$y \sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}} = f\left(x + y \frac{dy}{dx}\right) \dots\dots\dots (1).$$

Now the differential equations of the first order

$$x + y \frac{dy}{dx} = a \dots\dots\dots (2),$$

$$y \sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}} = b \dots\dots\dots (3),$$

are derivable from a common primitive; for, on differentiating them, we have respectively

$$1 + \left(\frac{dy}{dx}\right)^2 + y \frac{d^2y}{dx^2} = 0,$$

$$\frac{\frac{dy}{dx}}{\sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}}} \left\{1 + \left(\frac{dy}{dx}\right)^2 + y \frac{d^2y}{dx^2}\right\} = 0,$$

and these agree as differential equations of the second order, Chap. I. Art. 9. That common primitive, found by eliminating  $\frac{dy}{dx}$  between (2) and (3), is

$$y^2 + (x - a)^2 = b^2.$$

Hence the primitive of the given equation is

$$y^2 + (x - a)^2 = \{f(a)\}^2 \dots\dots\dots(4).$$

We might also proceed as in the solution of Clairaut's equation. Differentiating the given equation, we have

$$\left\{ \frac{\frac{dy}{dx}}{\sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}}} - f' \left( x + y \frac{dy}{dx} \right) \right\} \times \left\{ 1 + \left( \frac{dy}{dx} \right)^2 + y \frac{d^2y}{dx^2} \right\} = 0.$$

The second factor, which alone involves  $\frac{d^2y}{dx^2}$ , equated to 0, gives on integration the primitive

$$y^2 + (x - a)^2 = b^2,$$

as will be seen in Chap. x. Art. 1, in which the relation between  $b$  and  $a$  remains to be determined as before. The first factor equated to 0 constitutes the differential equation of the *singular solution*, which will be obtained by eliminating  $\frac{dy}{dx}$  between that equation and the equation given.

Clairaut's equation belongs to the above class. We may express it in the form

$$y - x \frac{dy}{dx} = f\left(\frac{dy}{dx}\right).$$

Now the differential equations

$$y - x \frac{dy}{dx} = a,$$

$$\frac{dy}{dx} = b,$$

generate the same differential equation of the second order

$$\frac{d^2y}{dx^2} = 0,$$

and are derivable from the same primitive

$$y = bx + a.$$

### *Examples of Transformation.*

10. Well-chosen transformations facilitate much the solution of differential equations of the first order.

Ex. 1. Given  $\frac{y - xp}{\sqrt{1 + p^2}} = f(x^2 + y^2)^{\frac{1}{2}}$ . *Lacroix*, Tom. II. p. 292.

Assuming  $x = r \cos \theta$ ,  $y = r \sin \theta$ , we have

$$\frac{-r^2}{\sqrt{\left\{r^2 + \left(\frac{dr}{d\theta}\right)^2\right\}}} = f(r),$$

whence

$$\frac{dr}{d\theta} = \frac{r \sqrt{[r^2 - \{f(r)\}^2]}}{f(r)}.$$

Consequently

$$\theta = \int \frac{f(r) dr}{r \sqrt{[r^2 - \{f(r)\}^2]}} + C.$$

As  $\frac{y - xp}{\sqrt{1 + p^2}}$  is the expression for the length of the perpendicular let fall from the origin upon the tangent to a curve, the above is the solution of the problem which proposes to determine the equation of a curve in which that perpendicular is a given function of the distance of the point of contact from the origin.

By the same transformation we may solve the equation

$$\frac{y - xp}{\sqrt{(1 + p^2)}} = \sqrt{(x^2 + y^2)} f\left\{\frac{x}{\sqrt{(x^2 + y^2)}}\right\}.$$

Ex. 2. Given  $\left(\frac{dy}{dx}\right)^k = Ax^\alpha + By^\beta$ .

To render the above equation homogeneous if possible let  $y = z^n$ ; we find

$$\left(nz^{n-1} \frac{dz}{dx}\right)^k = Ax^\alpha + Bz^{n\beta}.$$

This will be homogeneous with respect to  $z$  and  $x$ , if we have

$$k(n-1) = \alpha = n\beta,$$

equations from which we deduce

$$k = \frac{\alpha\beta}{\alpha - \beta}, \quad n = \frac{\alpha}{\beta},$$

the former of which expresses a condition between the indices of the given equation, the latter the value which must be given to  $n$  when that condition is satisfied.

It appears then that the equation

$$\left(\frac{dy}{dx}\right)^{\frac{\alpha\beta}{\alpha-\beta}} = Ax^\alpha + By^\beta,$$

can be rendered homogeneous by the assumption  $y = z^{\frac{\alpha}{\beta}}$ .

If the more general transformation  $y = z^n$ ,  $x = t^m$ , which seems at first sight to put us in possession of two disposable constants, be employed, the necessity for the fulfilment of the same condition between  $\alpha$ ,  $\beta$ , and  $k$ , will not be evaded, the ratio of the constants  $m$  and  $n$ , not their absolute values, proving to be alone available.

Ex. 3. The equation of the projection on the plane  $xy$  of the lines of curvature of the ellipsoid is

$$Axy \left(\frac{dy}{dx}\right)^2 + (x^2 - Ay^2 - B) \frac{dy}{dx} - xy = 0 \dots\dots(1).$$

Assuming  $x^2 = s$ ,  $y^2 = t$ , the equation is reduced to one of Clairaut's form, Art. 6. Its solution is

$$y^2 - Cx^2 = -\frac{BC}{AC + 1}.$$

The equation may also, without preliminary transformation, be integrated by Lagrange's method, Art. 9. We may express it in the form

$$A\phi\psi + B\phi + \psi = 0 \dots\dots\dots(2),$$

$$\text{where } \phi = \frac{yp}{x}, \quad \psi = y^2 - ypx.$$

$$\text{Now} \quad \frac{y}{x}p = a, \quad y^2 - ypx = b,$$

are derived from a common primitive  $y^2 - ax^2 = b$ . The solution of (2) will therefore be,

$$y^2 - ax^2 = b$$

with the connecting relation between the constants,

$$Aab + Ba + b = 0.$$

And this will be found to agree with the previous result.

### EXERCISES.

The following examples are chiefly in illustration of Arts. 1, 2, 3, 5.

$$1. \quad \left(\frac{dy}{dx}\right)^2 - 5\left(\frac{dy}{dx}\right) + 6 = 0.$$

$$2. \quad \left(\frac{dy}{dx}\right)^2 - \frac{a^2}{x^2} = 0.$$

$$3. \quad \left(\frac{dy}{dx}\right)^2 = \frac{1-x}{x}.$$

$$4. \quad \left(\frac{dy}{dx}\right)^2 + 2\frac{x}{y}\frac{dy}{dx} - 1 = 0.$$

$$5. \quad y = a\frac{dy}{dx} + b\left(\frac{dy}{dx}\right)^2.$$

$$6. \quad x = a\frac{dy}{dx} + b\left(\frac{dy}{dx}\right)^2.$$

$$7. \quad y = a\frac{dy}{dx} + \sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}}.$$

$$8. \quad x = a\frac{dy}{dx} + \sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}}.$$

$$9. \quad \frac{dy}{dx} - \frac{1}{x}\sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}} = 0.$$

$$10. \quad x^2 \left\{1 + \left(\frac{dy}{dx}\right)^2\right\}^3 - a^2 = 0.$$

$$11. \quad 1 + \left(\frac{dy}{dx}\right)^2 = \frac{(x+a)^2}{x^2 + 2ax}.$$

The following examples are intended to illustrate Art. 6. The singular solutions as well as the complete primitives are to be determined.

$$12. \quad y = x\frac{dy}{dx} + \frac{dy}{dx} - \left(\frac{dy}{dx}\right)^2.$$

$$13. \quad y = x\frac{dy}{dx} + \sqrt{\left\{b^2 - a^2\left(\frac{dy}{dx}\right)^2\right\}}.$$

The following examples are in illustration of Arts. 7 and 8.

$$14. \quad y = x\frac{dy}{dx} + x\sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}}.$$

$$15. \quad y = x \frac{dy}{dx} + ax \sqrt{1 + \left(\frac{dy}{dx}\right)^2}.$$

$$16. \quad x - y \frac{dy}{dx} = a \left(\frac{dy}{dx}\right)^2.$$

$$17. \quad x + y \frac{dy}{dx} = a \sqrt{1 + \left(\frac{dy}{dx}\right)^2}.$$

The following examples are in illustration of Art. 9.

$$18. \quad y \frac{dy}{dx} = x + f\left\{y^2 - y^2 \left(\frac{dy}{dx}\right)^2\right\}.$$

$$19. \quad y - \frac{1}{\sqrt{1 + \left(\frac{dy}{dx}\right)^2}} = f\left\{x + \frac{\frac{dy}{dx}}{\sqrt{1 + \left(\frac{dy}{dx}\right)^2}}\right\}.$$

$$20. \quad y - 2x \frac{dy}{dx} = f\left\{x \left(\frac{dy}{dx}\right)^2\right\}.$$

$$21. \quad \frac{y - x \frac{dy}{dx}}{y^2 + \frac{dy}{dx}} = f\left(\frac{y - x \frac{dy}{dx}}{1 + x^2 \frac{dy}{dx}}\right).$$

## CHAPTER VIII.

### ON THE SINGULAR SOLUTIONS OF DIFFERENTIAL EQUATIONS OF THE FIRST ORDER.

1. IN the largest sense which has been given to the term, a singular solution of a differential equation is a relation between the variables which reduces the two members of the equation to an identity, but which is not included in the complete primitive.

In this sense, the relation obtained by equating to 0 some common algebraic factor of the terms of the equation might claim to be called a singular solution.

But, in a juster and more restricted sense, a singular solution of a differential equation is a relation between  $x$  and  $y$ , which satisfies the differential equation *by means of the values which it gives to the differential coefficients*  $\frac{dy}{dx}$ ,  $\frac{d^2y}{dx^2}$ , &c., but is not included in the complete primitive. In this sense the equation  $x^2 + y^2 = n^2$ , is a singular solution of the differential equation of the first order

$$y - x \frac{dy}{dx} = n \sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}}.$$

It reduces the members of that equation to an identity, but not by causing any algebraic factor of them both to vanish. At the same time it is not included in the complete primitive

$$y - cx = n \sqrt{1 + c^2}.$$

And this is the juster definition, because that which is essential in the singular solution is thus in a direct manner connected with that which is essential in the differential equation. Def. Chap. I.

When it is said that a singular solution of a differential equation is not included in the complete primitive, it is meant that it is not deducible from that primitive by giving to the arbitrary constant  $c$  a particular constant value. But although a singular solution is not *included* in the complete primitive, it is still *implied* by it. Upon the possibility of satisfying a differential equation by an infinite number of particular equations, each formed by the particular determination of an arbitrary constant, rests the possibility of satisfying it by another equation, to the formation of which each particular solution has contributed an element. We have seen in Chap. VII. how a singular solution, as representing the envelope of the loci defined by the series of particular solutions, possesses a differential element common with each of them. We shall now see that this property is not accidental—that it is intimately connected with the definition of a singular solution.

It is important that the two marks, positive and negative, by the union of which a singular solution of a differential equation of the first order is characterized, and by the expression of which its definition is formed, should be clearly apprehended. 1st. It must give the same value of  $\frac{dy}{dx}$  in terms of  $x$  and  $y$ , as the differential equation itself does. This is its *positive* mark, a mark which it possesses in common with the complete primitive, and with each included particular primitive. 2ndly. It must not be included in the complete primitive. This is its negative mark. Upon the analytical expression of these characters the entire theory of this class of solutions depends.

Among the different objects to which that theory has reference, the two following are the most important. 1st. The derivation of the singular solution from the complete primitive. 2ndly. The deduction of the singular solution from the differential equation without the previous knowledge of the complete primitive. The theory of the latter process is so dependent upon that of the former that it is necessary to consider them in the order above stated.

[Important additions to the present Chapter are given in the *Supplementary Volume*, Chapter XXI.]

*Derivation of the singular solution from the complete primitive.*

2. The complete primitive of a differential equation of the first order, whatever may be the degree of the equation, is of the form

$$\phi(x, y, c) = 0.$$

If we give to  $c$  a particular constant value in this equation we obtain a particular primitive. If we give to  $c$  a variable value by making it a function of  $x$ , or of  $y$ , or of both, we, as will immediately be shewn, convert the equation into any desired relation between  $x$  and  $y$ . We propose then to determine  $c$  as variable, but as so varying that the resulting relation between  $x$  and  $y$  shall continue to satisfy the differential equation.

The general effect of the conversion of  $c$  into a function of  $x$  or of  $y$  must first be considered.

PROP. I. *A primitive equation*

$$\phi(x, y, c) = 0$$

*may, by the conversion of  $c$  into a function of  $x$ , be transformed into any desired equation containing  $x$  and  $y$  together, or  $y$  alone, but not into an equation involving  $x$  without  $y$ .*

Let the desired result of transformation be

$$\psi(x, y) = 0, \text{ or } \chi(y) = 0,$$

involving  $y$  at least. Combining either of these equations with the primitive we can eliminate  $y$ , and so obtain a relation between  $x$  and  $c$  which will determine  $c$  as the function of  $x$  required.

It is evident however that the conversion of  $c$  into a function of  $x$  could not convert the primitive into an equation not involving  $y$ . For a variable cannot be eliminated from an equation, except by the aid of another equation which contains that variable.

Similarly the conversion of  $c$  into a function of  $y$  would enable us to convert the given primitive into any desired equation involving, of the two variables, at least  $x$ .

Ex. Let it be required to convert the equation  $y = cx$  into  $x^2 + y^2 = 1$ , by the conversion of  $c$  into a function of  $x$ .

Eliminating  $y$  from the given and the proposed equation, we have

$$x^2 + c^2 x^2 = 1,$$

$$\text{whence } c = \frac{\sqrt{1 - x^2}}{x}.$$

This value of  $c$  substituted in  $y = cx$ , converts it into

$$y = \sqrt{1 - x^2},$$

which is equivalent to  $x^2 + y^2 = 1$ .

3. Let us now enquire what determination of  $c$  as a function of  $x$  will convert the primitive  $\phi(x, y, c) = 0$  into a relation between  $x$  and  $y$  still satisfying the differential equation.

Now the complete primitive of a differential equation of the first order is always by solution with respect to  $y$  reducible either to a single equation or to a series of equations of the form

$$y = f(x, c) \dots\dots\dots(1).$$

If we differentiate, regarding  $c$  as constant, we have as the derived equation

$$\frac{dy}{dx} = \frac{df(x, c)}{dx} \dots\dots\dots(2),$$

and the elimination of  $c$  from this by means of the previous equation gives us a value of  $\frac{dy}{dx}$  which satisfies the differential equation. That differential equation would then still be satisfied if  $c$  were regarded as variable, provided that the variation were such as to leave unchanged the form of the relation be-

tween  $x$ ,  $y$  and  $c$  in the primitive and in the derived equation. For the nature of  $c$  does not affect the *mode* of the elimination.

Differentiating (1) then on the hypothesis that  $c$  is a function of  $x$ , and representing the differential coefficient of  $c$  thus considered by  $\left(\frac{dc}{dx}\right)$ , we have

$$\frac{dy}{dx} = \frac{df(x, c)}{dx} + \frac{df(x, c)}{dc} \left(\frac{dc}{dx}\right) \dots\dots\dots (3).$$

And this will agree in form with the expression for  $\frac{dy}{dx}$  in (2) if  $\frac{df(x, c)}{dc} \left(\frac{dc}{dx}\right) = 0$ . But to suppose  $\left(\frac{dc}{dx}\right) = 0$  would be to suppose  $c$  a constant and to return to the ordinary primitive. It remains therefore that for a singular solution we have

$$\frac{df(x, c)}{dc} = 0, \quad \text{or} \quad \frac{dy}{dc} = 0 \dots\dots\dots (4).$$

This is the first analytical condition. What it means is that if a fixed value be given to  $x$  in the primitive,  $y$  must not vary for an infinitesimal variation of  $c$ . And by this condition  $c$  is to be determined as a function of  $x$ .

Now in accordance with the reasoning of Prop. I. the substitution of a function of  $x$  for  $c$  in a primitive which contains  $y$ , cannot lead to a resulting equation not containing  $y$ , though it may lead to a resulting equation not containing  $x$ . Hence the condition  $\frac{dy}{dc} = 0$  can only lead to those singular solutions in the expression of which  $y$  at least is involved. Had we reduced the primitive to the form  $x = f(y, c)$  we should, as is evident from the principle of symmetry, have arrived at the analytical condition

$$\frac{dx}{dc} = 0 \dots\dots\dots (5),$$

a condition by which  $c$  would be determined as a function of

$y$ . And the substitution of such value or values of  $c$  in the primitive would lead to all singular solutions in the expression of which  $x$  at least is involved.

It will be remembered that what is essential to a singular solution is that  $c$  should not admit of determination as a constant wholly independent of the variables. But whether it be determined as a function of  $x$  or as a function of  $y$  is indifferent. The one form is usually, but not always, convertible into the other by means of the primitive. Thus, if the primitive be in the form  $\phi(x, y, c) = 0$ , and  $c$  be determined in the form  $c = f(y)$ , the elimination of  $y$  between these equations will generally enable us to determine  $c$  as a function of  $x$ ; but it will not do so if, in the elimination of  $y$ ,  $c$  should disappear.

Thus if the primitive were

$$x = (y - c)^2,$$

the value of  $c$  determined as a function of  $y$  by the condition  $\frac{dx}{dc} = 0$  would be  $c = y$ , and *this* value of  $c$  is not expressible by means of  $x$ , for on attempting to eliminate  $y$  between the above equations  $c$  also disappears. Nor is it indeed possible in the above case to satisfy the condition  $\frac{dy}{dc} = 0$ . Hence it is necessary in establishing a general method to take account of *both* the conditions (4) and (5).

And these conditions are sufficient. No other is implied. The comparison of (2) and (3), from which the condition  $\frac{dy}{dc} = 0$  was derived, leads also to the condition  $\frac{dx}{dc} = 0$ , but not to any other condition. The expressions which they furnish for  $\frac{dy}{dx}$  become equivalent in two cases only, viz. 1st, if  $\frac{df(x, c)}{dc} = 0$ , the case first considered; 2ndly, if without supposing

$\frac{df(x, c)}{dc} = 0$ , we have  $\frac{df(x, c)}{dc} \left(\frac{dc}{dx}\right)$  infinitesimal in comparison with  $\frac{df(x, c)}{dx}$ , and therefore if we have

$$\frac{df(x, c)}{dc} \div \frac{df(x, c)}{dx} = 0 \dots\dots\dots(6),$$

for,  $c$  being regarded as a function of  $x$ , and therefore variable, the factor  $\left(\frac{dc}{dx}\right)$  cannot be continuously infinite. Now differentiating the equation  $y = f(x, c)$  we have

$$dy = \frac{df(x, c)}{dx} dx + \frac{df(x, c)}{dc} dc \dots\dots\dots(7).$$

Hence, if we make  $dy = 0$ , we have

$$\frac{dx}{dc} = -\frac{df(x, c)}{dc} \div \frac{df(x, c)}{dx} \dots\dots\dots(8),$$

so that (6) assumes the form  $\frac{dx}{dc} = 0$ . But, as a *demonstration* of this condition, the above method is less general than the previous one, for it assumes the possibility of expressing as a function of  $x$  the value of  $c$  determined by the condition  $\frac{dx}{dc} = 0$ . Now that value is primarily a function of  $y$ , and may not be expressible at all by means of  $x$ .

It is well to note that the final criteria  $\frac{dy}{dc} = 0$ ,  $\frac{dx}{dc} = 0$  are in effect analytical expressions of what logicians term conditional propositions. The former expresses that *if*  $x$  be assumed constant,  $y$  will not vary for an infinitesimal variation of  $c$ ; the latter, that *if*  $y$  be assumed constant,  $x$  will not vary for an infinitesimal variation of  $c$ .

4. Each of these conditions then

$$\frac{dy}{dc} = 0, \quad \frac{dx}{dc} = 0,$$

has its special case of failure. The former cannot lead us to

singular solutions in which  $y$  is not involved; the latter cannot lead to those in which  $x$  is not involved. It is proper to shew that except in such cases of failure they are equivalent.

As expressed by means of the primitive  $y = f(x, c)$ , these conditions assume the forms

$$\frac{df(x, c)}{dc} = 0, \quad \frac{df(x, c)}{dc} \div \frac{df(x, c)}{dx} = 0,$$

or 
$$\frac{dy}{dc} = 0, \quad \frac{dy}{dc} \div \frac{dy}{dx} = 0,$$

and these are equivalent unless  $\frac{dy}{dx}$  be 0 or infinite.

But  $\frac{dy}{dx} = 0$  implies that the singular solution is of the form

$$y = \text{a definite constant},$$

and this is precisely that form of singular solution which the condition  $\frac{dx}{dc} = 0$  fails to give.

Similarly  $\frac{dy}{dx} = \infty$ , being equivalent to  $\frac{dx}{dy} = 0$ , implies that the singular solution is of the form

$$x = \text{a definite constant},$$

and this is that form of singular solution which the condition  $\frac{dy}{dc} = 0$  fails to give.

Thus the conditions  $\frac{dy}{dc} = 0$ ,  $\frac{dx}{dc} = 0$ , although not necessarily equivalent, do not lead to *conflicting* results.

When we cannot solve the primitive equation with respect to  $y$  and  $x$  so as to enable us to form directly the expressions

for  $\frac{dy}{dc}$  and  $\frac{dx}{dc}$ , we may proceed thus. Representing the primitive by  $\phi = 0$ , we have on differentiation

$$\frac{d\phi}{dx} dx + \frac{d\phi}{dy} dy + \frac{d\phi}{dc} dc = 0.$$

Hence, remembering what is meant by  $\frac{dy}{dc}$  and  $\frac{dx}{dc}$ ,

$$\frac{dy}{dc} = -\frac{\frac{d\phi}{dc}}{\frac{d\phi}{dy}}, \quad \frac{dx}{dc} = -\frac{\frac{d\phi}{dc}}{\frac{d\phi}{dx}} \dots\dots\dots (9),$$

and the second members of these equations must be equated to 0.

We see that these second members will usually vanish if  $\frac{d\phi}{dc} = 0$ . And this equation  $\frac{d\phi}{dc} = 0$  is adopted by some writers as a sufficient expression of the rule for the derivation of the singular solution from the complete primitive, unrestricted by any accompanying condition. (Lagrange, *Calcul des Fonctions*, p. 207.) We must notice however that the vanishing of  $\frac{dy}{dc}$  or  $\frac{dx}{dc}$  in (9) may be due not to the vanishing of the

numerator  $\frac{d\phi}{dc}$ , but to the assumption of an infinite value by the denominator  $\frac{d\phi}{dy}$  or  $\frac{d\phi}{dx}$ . The latter is indeed quite as probable a cause as the former when  $\phi$  is not expressed as a rational and integral function of  $x$  and  $y$ . And even when  $\phi$  is thus expressed the condition  $\frac{d\phi}{dc} = 0$  may fail through its involving a factor contained in  $\frac{d\phi}{dy}$  or  $\frac{d\phi}{dx}$ . We conclude that

while the true tests of a singular solution are  $\frac{dy}{dc} = 0$  and  $\frac{dx}{dc} = 0$ , any subsidiary conditions such as  $\frac{d\phi}{dc} = 0$ ,  $\frac{d\phi}{dy} = \infty$ ,

$\frac{d\phi}{dx} = \infty$ , are only to be used for purposes of convenience, and never without reference to the more fundamental relations of which they take the place.

The following is a legitimate example of the application of the subsidiary condition  $\frac{d\phi}{dc} = 0$ .

The complete primitive of the differential equation  $\frac{dy}{dx} = 2y^{\frac{1}{2}}$  is  $y = (x - c)^2$ . Here  $\phi = y - (x - c)^2$ , and, this being rational and integral, the condition  $\frac{d\phi}{dc} = 0$  gives  $2(x - c) = 0$ , whence  $c = x$ , a value of which, substituted in the primitive, gives  $y = 0$  a singular solution.

The condition  $\frac{dy}{dc} = 0$  also gives  $c = x$ , and leads to the same result. But, since the primitive solved with respect to  $x$  gives  $x = c + y^{\frac{1}{2}}$ , the condition  $\frac{dx}{dc} = 0$  cannot be satisfied. Thus the singular solution is here obtained by means of the condition  $\frac{dy}{dc} = 0$ , and not by the condition  $\frac{dx}{dc} = 0$ .

5. The chief results of the above investigation are combined in the following Proposition.

PROP. II. *Every singular solution of a differential equation of the first order may be deduced from its complete primitive by giving therein to  $c$  a variable value determined from that primitive by either or both of the equations*

$$\frac{dy}{dc} = 0, \quad \frac{dx}{dc} = 0 \dots \dots \dots (1).$$

*And any solution which is thus obtained, and which cannot be also obtained by giving to  $c$  in the primitive a constant value, is a singular solution.*

*The conditions (1) are equivalent, except when one only of the variables  $x$  and  $y$  is involved in the singular solution; solu-*

tions involving only the variable  $y$  resulting only from the condition  $\frac{dy}{dc} = 0$ , and those involving only the variable  $x$  resulting only from the condition  $\frac{dx}{dc} = 0$ .

When the primitive, represented by  $\phi = 0$ , is rational and integral we may for convenience employ the single condition  $\frac{d\phi}{dc} = 0$ ; but never without reference to the fundamental conditions (1).

In the statement of the above theorem the two following particulars should be noticed.

1st. It supposes  $c$  to be determined as a variable quantity. Now if  $c$  be obtained as a function of both  $x$  and  $y$ , as it generally will be if the condition  $\frac{d\phi}{dc} = 0$  be made use of, it may be necessary by a subsequent elimination to reduce it to a function of *one* of the variables, in order to assure ourselves that it is not constant in virtue of the relation between  $x$  and  $y$  established in the primitive.

2ndly. The theorem takes account equally of the positive and of the negative characters of a singular solution. The existence of a variable value of  $c$  determined by either of the conditions (1) does not assure us that the resulting solution is singular, unless constant values of  $c$  are at the same time excluded.

Ex. 1. The equation  $y^2 - 2xy \frac{dy}{dx} + (1 + x^2) \left(\frac{dy}{dx}\right)^2 = 1$ , has for its complete primitive  $y = cx + \sqrt{1 - c^2}$ . Its singular solution is required.

Here  $\frac{dy}{dc} = x - \frac{c}{\sqrt{1 - c^2}}$ . Hence  $\frac{dy}{dc} = 0$  gives for  $c$  the *variable* value  $c = \frac{x}{\sqrt{x^2 + 1}}$ , the substitution of which in the primitive gives

$$y = \sqrt{x^2 + 1} \dots\dots\dots(1).$$

This value of  $y$  satisfies the given differential equation, and it is evident on inspection that it is not included in the complete primitive. Formally to establish this, we find on eliminating  $y$  between that equation and (1)

$$cx + \sqrt{(1 - c^2)} = \sqrt{(x^2 + 1)};$$

solving which with respect to  $c$ , we have the unique value  $c = \frac{x}{\sqrt{(x^2 + 1)}}$ , which, agreeing with the value of  $c$  before employed, shews that  $c$  admits of no other value, and in particular that it admits of no constant value. The solution is therefore singular.

The condition  $\frac{dx}{dc} = 0$  would, in the above example, give  $c = \frac{(y^2 - 1)^{\frac{1}{2}}}{y}$ , and lead to the same final result.

We must be careful not to rely upon the condition  $\frac{d\phi}{dc} = 0$ , except under the circumstances specified in the general theorem. This remark will be illustrated in the following example.

Ex. 2. The complete primitive of the differential equation  $y = px + \frac{m}{p}$ , where  $p$  stands for  $\frac{dy}{dx}$ , is  $y - cx - \frac{m}{c} = 0$ , and, if we represent its first member by  $\phi$ , the elimination of  $c$  between the equations  $\phi = 0$ ,  $\frac{d\phi}{dc} = 0$ , gives the singular solution  $y^2 = 4mx$ .

But, though this is not a procedure likely to be adopted, if we reduce the primitive by solution to the form

$$\frac{y \pm \sqrt{(y^2 - 4mx)}}{x} - 2c = 0,$$

and then represent its first member by  $\phi$ , we shall have

$$\begin{aligned}\frac{dy}{dc} &= -\frac{d\phi}{dc} \div \frac{d\phi}{dy} \\ &= 2 \div \left\{ \frac{1}{x} \pm \frac{y}{x\sqrt{(y^2 - 4mx)}} \right\}.\end{aligned}$$

And here the singular solution  $y^2 - 5mx = 0$ , before obtained, is seen to be dependent, not upon the vanishing of  $\frac{d\phi}{dc}$ , but upon the assumption of an infinite value by  $\frac{d\phi}{dy}$ .

The true ground of preference for the conditions  $\frac{dy}{dc} = 0$ ,  $\frac{dx}{dc} = 0$ , consists, however, not in the directness of their application to irrational forms of the primitive, but in the plainness of their geometrical interpretation, and still more in their fundamental relation to the problem of the derivation of the singular solution from the differential equation—questions hereafter to be discussed.

The following example is intended to illustrate that portion of the theorem which relates to the negative character of a singular solution.

Ex. 3. The complete primitive of the differential equation

$$\left(\frac{dy}{dx}\right)^3 - 4xy \frac{dy}{dx} + 8y^2 = 0,$$

is  $y = c(x - c)^2$ . The singular solution is required.

Here the condition  $\frac{dy}{dc} = 0$  gives

$$(x - c)(x - 3c) = 0,$$

whence  $c = x$ , or  $\frac{x}{3}$ . These values of  $c$ , both of which are variable, reduce the primitive to the forms

$$y = 0, \quad y = \frac{4x^3}{27},$$

and both these are solutions of the differential equation. But while the latter of the two is not included in the complete primitive, the former is included in it. If between the equations

$$y = c(x - c)^2, \quad y = 0,$$

we eliminate  $y$ , the resulting values of  $c$  will be

$$c = 0, \quad c = x.$$

We see therefore that the solution to which we were led by the assumption  $c = x$  is a particular integral. But it possesses the geometrical properties of a singular solution explained in the following Article.

### *Geometrical Interpretation.*

6. Let  $y = f(x, c)$  represent a family of curves the individual members of which are determined by giving different values to  $c$ . Then, adopting for a moment the language of infinitesimals, the differentiation of  $y$  with respect to  $c$  implies the transition from an ordinate  $y$  of one curve to an ordinate  $y + \frac{dy}{dc} dc$ , corresponding to the *same* value of  $x$ , but belonging to another curve of the series; viz. the curve obtained by changing  $c$  into  $c + dc$ .

When we impose the condition  $\frac{dy}{dc} = 0$ , we demand that this transition shall not affect the value of the ordinate  $y$  corresponding to a value of  $x$  determined by the equation  $\frac{dy}{dc} = 0$ .

Hence the singular equation obtained by the elimination of  $c$  between the equations  $y = f(x, c)$ ,  $\frac{dy}{dc} = 0$ , represents the *locus* of such points of successive intersection.

In stricter language, the singular solution represents the locus of those points which constitute the *limits* of position of the points of *actual* intersection of the different members of the family of curves represented by the equation  $y = f(x, c)$ , always excepting the case in which that locus coincides with a particular curve of the system.

And as at these limiting points the value of  $\frac{dy}{dx}$  is the same for the locus of the singular solution and the loci of primitives, it follows that the former has *contact* with every curve of the latter system which it meets. The locus of the singular solution is seen to be the envelope of the loci of primitives. The envelope of the loci of primitives is the locus of a singular solution, except when it coincides with one of the particular loci, of which it forms the connecting bond.

Similar observations may be made with reference to the condition  $\frac{dx}{dc} = 0$ .

*Derivation of the singular solution from the differential equation.*

7. We have found that the singular solution of a differential equation considered as derived from its complete primitive possesses the following characters.

1st. It satisfies one of the conditions  $\frac{dy}{dc} = 0$ ,  $\frac{dx}{dc} = 0$ .

2nd. It is not possible to deduce it from the complete primitive by giving to  $c$  a constant value.

It has also been shewn that the positive conditions are equivalent except when the singular solution involves only one of the variables in its expression.

Now we shall endeavour to translate the above characters from a language whose elements are  $x, y$ , and  $c$  to a language whose elements are  $x, y$ , and  $\frac{dy}{dx}$ ,—from the language of the complete primitive to the language of the differential equation.

If we differentiate with respect to  $x$  the complete primitive expressed in the form

$$y = f(x, c) \dots \dots \dots (1),$$

we obtain the *derived* equation

$$p = \frac{df(x, c)}{dx} \dots \dots \dots (2),$$

and substituting in this for  $c$  its expression in terms of  $x$  and  $y$  given by the primitive (1), we have finally the *differential equation* in the form

$$p = \phi(x, y) \dots \dots \dots (3).$$

Thus the differential equation (3) is the same as the derived equation (2), provided that  $c$  be considered therein as a function of  $x$  and  $y$  determined by (1).

Accordingly we have

$$\frac{dp}{dy} \text{ in (3)} = \frac{dp}{dc} \text{ in (2)} \times \frac{dc}{dy} \text{ in (1)},$$

or 
$$\frac{dp}{dy} \text{ in (3)} = \frac{d^2f(x, c)}{dx dc} \div \frac{df(x, c)}{dc};$$

since in (1) 
$$\frac{dc}{dy} = 1 \div \frac{dy}{dc} = 1 \div \frac{df(x, c)}{dc}.$$

Hence 
$$\frac{dp}{dy} \text{ in (3)} = \frac{d}{dx} \log \frac{df(x, c)}{dc},$$

or finally 
$$\frac{dp}{dy} = \frac{d}{dx} \log \frac{dy}{dc} \dots \dots \dots (4),$$

provided that the value of the first member be derived from the differential equation, that of the second member from the complete primitive.

In like manner if we suppose the complete primitive expressed in the form

$$x = \phi(y, c),$$

we shall have through symmetry the relation

$$\frac{d}{dx} \left( \frac{1}{p} \right) = \frac{d}{dy} \log \frac{dx}{dc} \dots\dots\dots (5),$$

the first member referring to the differential equation, the second to the complete primitive.

The equations (4) and (5), which are rigorous and fundamental, establish a connexion between the differential equation and the complete primitive, and it now only remains to introduce the conditions  $\frac{dy}{dc} = 0$ ,  $\frac{dx}{dc} = 0$ . We begin with the former.

We have seen that when  $\frac{dy}{dc} = 0$  leads to a singular solution it does so by enabling us to determine  $c$  as a function of  $x$ , suppose  $c = X$ . Before proceeding to more general considerations it will be instructive to make a particular hypothesis as to the *form* of the equation  $\frac{dy}{dc} = 0$ .

Suppose then this equation to be of the form

$$Q(c - X)^m = 0 \dots\dots\dots (6),$$

$m$  being a positive constant and  $Q$  a function of  $x$  and  $c$ , which neither vanishes nor becomes infinite when  $c = X$ . This hypothesis is at least sufficiently general to include all the cases in which  $\frac{dy}{dc} = 0$  is algebraic.

By (6) we have then

$$\frac{dp}{dy} = \frac{d}{dx} \log \frac{dy}{dc} = \frac{\frac{dQ}{dx}}{Q} - m \frac{\frac{dX}{dx}}{c - X} \dots\dots\dots (7),$$

and the second term of the right-hand member having  $c - X$  for its denominator and not containing  $c$  at all in its numerator, is infinite. At the same time, we see that no such infinite term would present itself were  $c$  determined as a constant.

For let  $\frac{dy}{dc} = Q (c - \alpha)^m$ , then  $\frac{d}{dx} \log \frac{dy}{dc} = \frac{dQ}{dx} \div Q$ , the right-hand member of (7) being now reduced to its first term.

The conclusion to which this points is that  $\frac{dp}{dy}$  is infinite for a singular solution, but finite for a particular integral.

Again, suppose the value of  $c$  in terms of  $x$  and  $y$  furnished by algebraic solution of the complete primitive to be  $c = \phi(x, y)$ , then substituting this value in the equation  $c - X = 0$ , we obtain the singular solution in the form

$$\phi(x, y) - X = 0.$$

Now the same substitution gives to the infinite term in the value of  $\frac{dp}{dy}$  the form

$$\frac{-m \frac{dX}{dx}}{\phi(x, y) - X} \dots\dots\dots (8).$$

We see then, in the case of a singular solution corresponding to a determination  $c = X$ , that  $\frac{dp}{dy}$  as derived from the differential equation becomes infinite owing to  $\phi(x, y) - X$  occurring in a denominator. And, whatever modification of form may be made by clearing of fractions or radicals, we may still infer that, if  $u = 0$  be a singular solution derived from an

algebraic primitive, the function  $\frac{dp}{dy}$  will become infinite, owing to  $u$  presenting itself under a negative index.

The analysis does not however warrant the conclusion that *any* relation between  $x$  and  $y$  which makes  $\frac{dp}{dy}$  infinite will be a solution. If  $m$  be a negative constant, the second term in the expression of  $\frac{dp}{dy}$  is still infinite, but the prior condition  $\frac{dy}{dc} = 0$  is no longer satisfied. All we can affirm is that if  $\frac{dp}{dy} = \infty$  gives a solution at all it will be a singular solution.

Since  $\frac{dx}{dy} = \frac{1}{p}$ , it is evident that a singular solution originating in a determination of  $c$  in the form  $c = Y$  will make  $\frac{d}{dx} \left( \frac{1}{p} \right)$  infinite.

A contrast between the conditions  $\frac{dy}{dc} = 0$ ,  $\frac{dx}{dc} = 0$ , and the conditions  $\frac{dp}{dy} = \infty$ ,  $\frac{d}{dx} \left( \frac{1}{p} \right) = \infty$ , is also developed. The former lead to solutions, but not necessarily to singular solutions; the latter do not necessarily lead to solutions, but when they do, those solutions are singular.

Ex. 1. Given  $p^2 - 2xp + 2y = 0$ .

Here  $p = x \pm \sqrt{(x^2 - 2y)}$ ,

$$\frac{dp}{dy} = \mp (x^2 - 2y)^{-\frac{1}{2}},$$

which becomes infinite if  $y = \frac{x^2}{2}$ , and this satisfies the differential equation. It is therefore a singular solution.

It may be objected against the above reasoning, not only that it involves an assumption as to the form of the equa-

tion  $\frac{dy}{dc}=0$ , but also that it takes no account of any possibilities arising from the first term in the expression of  $\frac{dp}{dy}$ . But it serves well to illustrate what, in the vast majority of instances, is the *actual* mode of transition from the one set of conditions to the other. We proceed to consider the question in a more strict and general manner.

8. When  $\frac{dy}{dc}=0$  determines  $c$  as a function of  $x$ , it reciprocally determines  $x$  as a function of  $c$ , so that if a definite value be given to  $c$ , a corresponding definite value or values will be given to  $x$ . Let  $\frac{dy}{dc}$  be represented by  $\psi(x, c)$ , then

$$\begin{aligned}\frac{dp}{dy} &= \frac{d}{dx} \log \frac{dy}{dc} \\ &= \text{limit of } \frac{\log \psi(x+h, c) - \log \psi(x, c)}{h} \dots\dots\dots(9),\end{aligned}$$

$h$  approaching to 0.

Now for a singular solution  $\psi(x, c)=0$ , and this being, from what precedes, satisfied only by definite values of  $x$ , corresponding to our assumed definite value of  $c$ , it follows that  $\psi(x+h, c)$  will not be equal to 0 for any continuous series of values of  $h$  however small; neither then will  $\log \psi(x+h, c)$  retain continuously the value of  $\log \psi(x, c)$ , viz.  $-\infty$ . Thus the numerator of the fraction in the second member being equal to the difference between a finite and an infinite quantity is infinite, and the limit of the fraction therefore infinite. Hence we conclude that a singular solution considered as derived from the primitive by the conversion of  $c$  into a function of  $x$ , satisfies relatively to the differential equation the condition

$$\frac{dp}{dy} = \infty.$$

And in the same way it may be shewn that a singular solution derivable from the primitive by the conversion of  $c$  into a function of  $y$  satisfies the condition  $\frac{d}{dx} \left( \frac{1}{p} \right) = \infty$ .

Changing the order of the enquiry, let us now examine whether there exist any other forms of solution satisfying the condition  $\frac{dp}{dy} = \infty$ ,  $\frac{d}{dx} \left( \frac{1}{p} \right) = \infty$ . If there be, it will be made evident that more is involved in the definition of a singular solution than we have yet recognized in our processes of deduction, or else that the definition must be enlarged.

Expressing the condition  $\frac{dp}{dy} = \infty$ , in the form

$$\frac{d}{dx} \log \frac{dy}{dc} = \infty \dots\dots\dots (10),$$

we observe that it can be satisfied only in one of two ways, viz. either independently of  $c$ , or by some determination of  $c$ , and if the latter again only in one of two ways, viz. either by the determination of  $c$  as a function of  $x$ , or by the determination of  $c$  as a constant.

We may pass over the case in which the above equation is satisfied independently of  $c$ , because the relation obtained would involve  $x$  only, whereas it has been shewn that  $\frac{dp}{dy} = \infty$  leads only to solutions involving  $y$  at least. We may also pass over the case in which it is satisfied by the assumption  $c = X$ , because such a value of  $c$ , if it lead to a solution at all, can only do so by satisfying the condition  $\frac{dy}{dc} = 0$ , and thus lead to the form of singular solution already investigated. There remains only the case in which the equation (10) is satisfied by a constant value of  $c$ .

Let then the equation (10) be satisfied by  $c = a$ . The most general assumption we can make respecting the form of its first member is the following, viz.

$$\frac{d}{dx} \log \frac{dy}{dc} = \phi(c) \psi(x, c),$$

where  $\phi(c)$  is a function of  $c$  which becomes infinite when  $c$

assumes the constant value in question, and  $\psi(x, c)$  does not become infinite for such value. Hence the most general form of  $\log \frac{dy}{dc}$  is

$$\log \frac{dy}{dc} = \int \phi(c) \psi(x, c) dx = \phi(c) \int \psi(x, c) dx.$$

To give to this expression the utmost generality, we must, on effecting the integration with respect to  $x$ , add an arbitrary function of  $c$ . Thus we shall have

$$\log \frac{dy}{dc} = \phi(c) \left\{ \int \psi(x, c) dx + \chi(c) \right\}.$$

Therefore 
$$\frac{dy}{dc} = e^{\phi(c) \left\{ \int \psi(x, c) dx + \chi(c) \right\}},$$

or, representing the function  $\int \psi(x, c) dx + \chi(c)$  by  $\Phi(x, c)$ ,

$$\frac{dy}{dc} = e^{\phi(c) \Phi(x, c)} \dots\dots\dots (11).$$

This is the most general form of  $\frac{dy}{dc}$ , as determined from the primitive, which is consistent with the hypothesis that  $\frac{d}{dx} \log \frac{dy}{dc}$  becomes infinite for a constant value of  $c$ . Accordingly if, supposing the primitive to be given, we sought to determine the singular solution by the condition  $\frac{dy}{dc} = 0$ , we should be led to an equation of the form

$$e^{\phi(c) \Phi(x, c)} = 0,$$

or 
$$\phi(c) \Phi(x, c) = -\infty \dots\dots\dots (12).$$

Now this equation is not satisfied by any value of  $c$  which makes  $\phi(c)$  infinite, unless it give to  $\Phi(x, c)$  an opposite sign

to that of  $\phi(c)$ . But this indicates in general the existence of a *relation* between  $x$  and  $c$ . Thus suppose

$$\phi(c) = c, \quad \Phi(x, c) = x.$$

Then (12) becomes

$$cx = -\infty,$$

which demands that  $c$  should receive the value  $-\infty$  or  $+\infty$ , according as  $x$  is positive or negative. In either case  $c$  is constant, but it is a *dependent* constant—dependent for its sign upon the sign of  $x$ . Thus the condition  $\frac{dp}{dy} = \infty$  may indicate the existence of a species of singular solution derived from the complete primitive by regarding  $c$ , not as a continuous function of  $x$ , but as a discontinuous constant, the law of its discontinuity being however such as to connect it with the variations of  $x$ .

Ex. 2. Given  $p = \frac{y \log y}{x}$ .

Here we find

$$\frac{dp}{dy} = \frac{1}{x} (1 + \log y) \dots \dots \dots (13),$$

which is infinite if  $y = 0$ . And this proves on trial to be a solution of the differential equation, the true value of the indeterminate function in the second member when  $y = 0$  being 0 (Todhunter's *Diff. Cal.* Art. 158). Now the complete primitive is  $y = e^{cx}$ . Hence we see that  $y = 0$  is not a particular integral in the strict sense of that term. The value to be assigned to  $c$  is not *wholly* independent of  $x$ . We may therefore regard  $y = 0$  as a singular solution satisfying the condition  $\frac{dp}{dy} = \infty$ .

9. We have said that, in general, the equation (12) indicates the existence of a relation between  $x$  and  $c$ . A case of exception however exists. Representing  $\phi(c)$  by  $C$ , suppose  $\Phi(x, c)$ , expressed in terms of  $x$  and  $C$ , to be capable of development in descending powers of  $C$ : suppose, too, that

the first term of the development is of the form  $AC^r$ , where  $A$  is constant and  $r > -1$ . Then as  $C$  approaches infinity, (12) tends to assume the form

$$AC^{r+1} = -\infty,$$

indicating that  $C$ , and therefore  $c$ , possesses more than one value, real or imaginary. Here, then, the condition  $\frac{dp}{dy} = \infty$  would accompany a solution possessing this singularity, viz. that it corresponds to a *multiple value* of  $c$ , the arbitrary constant in the complete primitive. It is in fact a species of *multiple particular integral*.

Ex. 3. Given  $p^2 - pxy + y^2 \log y = 0$ .

Here 
$$p = \frac{xy \pm y \sqrt{(x^2 - 4 \log y)}}{2};$$

therefore

$$\frac{dp}{dy} = \frac{x \pm \sqrt{(x^2 - 4 \log y)}}{2} \mp \frac{1}{\sqrt{(x^2 - 4 \log y)}} \dots \dots (14),$$

and this is made infinite by  $y = 0$  and by  $x^2 - 4 \log y = 0$ , that

is by 
$$y = 0, \quad y = e^{\frac{x^2}{4}}.$$

Both these satisfy the differential equation, and the second is obviously a singular solution. To determine the nature of the first let it be observed that the complete primitive is

$$y = e^{cx - c^2},$$

and that this reduces to  $y = 0$ , irrespectively of the value of  $x$ , by the assumptions  $c = +\infty$  and  $c = -\infty$ . Now this is the *only* case in which two particular integrals agree. We might in *any* case, by changing in the complete primitive of an equation  $c$  into  $c^2$ , get two values of  $c$  for a particular integral, but then it would be for *every* particular integral. It is only when the property is *singular*, that the condition  $\frac{dp}{dy} = \infty$  is satisfied.

It is obvious that one negative feature marks all the cases in which a solution involving  $y$  satisfies the condition  $\frac{dp}{dy} = \infty$ . It is, that the solution, while expressed by a single equation, is not connected with the complete primitive by a single and absolutely constant value of  $c$ . In the first, or as it might be termed *envelope* species of singular solutions,  $c$  receives an infinite number of different values connected with the values of  $x$  by a law. In the second it receives a finite number of values also connected with the values of  $x$  by a law. In the third species it receives a finite number of values, determinate, but not connected with the values of  $x$ .

If we observe that all the above cases, while agreeing in the point which has been noted, possess true singularity, we shall be led to the following definition.

DEFINITION. A singular solution of a differential equation of the first order is a solution, the connexion of which with the complete primitive does not consist in the giving to  $c$  of a single constant value absolutely independent of the value of  $x$ .

### *Criterion of species.*

10. It is a question of some interest to determine whether a given singular solution,  $u=0$ , of a differential equation, is of the envelope species or not.

On the particular hypotheses assumed in Art. 7, it is shewn that singular solutions of the envelope species possess the following character, viz. if  $u=0$  be such a solution, then  $\frac{dp}{dy}$  becomes infinite though containing a term in which  $u$  is presented under a negative index.

Now inquiries which are scarcely of a sufficiently elementary character to find a place in this work, indicate (with very high probability) that this character is universal and independent of any particular hypothesis, and that it constitutes a *criterion* for distinguishing solutions of the envelope species from others.

As an example of an hypothesis different from that of Art. 7, let us suppose

$$\frac{dy}{dc} = \frac{Q}{\log(c - X)},$$

which vanishes when  $c = X$ .

We find

$$\frac{d}{dx} \log \frac{dy}{dc} = \frac{\frac{dQ}{dx}}{Q} + \frac{\frac{dX}{dx}}{(c - X) \log(c - X)}.$$

The second term in the right-hand member becomes indeterminate when  $c = X$ , but its true value is  $\infty$ , and it assumes this value in consequence of  $c - X$  presenting itself with a negative index. We remark that the fraction  $\frac{1}{\log(c - X)}$  is one which vanishes with  $c - X$  in *whatever manner*  $c - X$  approaches to 0,—a consideration which is quite of essential importance.

Applying the above criterion to some of the previous examples, we see from the form of  $\frac{dp}{dy}$  in Ex. 1, Art. 7, that the singular solution belongs to the envelope species; in (13) Art. 8, it is implied that the solution is not of that species; in (14) Art. 9 two species are indicated, the solution  $y = 0$  resulting from  $\log y = -\infty$  being not of the envelope species, while the other solution is of that species.

11. The collected results of the above analysis are contained in the following theorem.

**THEOREM.** *The singular solutions of a differential equation of the first order (Def. Art. 9) consist of all relations which belong to one or both of the following classes, viz.*

1st. *Relations involving  $y$ , with or without  $x$ , which make  $\frac{dp}{dy}$  infinite and only infinite, and satisfy the differential equation.*

2nd. *Relations involving  $x$ , with or without  $y$ , which make  $\frac{d}{dx} \left( \frac{1}{p} \right)$  infinite and only infinite, and satisfy the differential equation.*

*When a solution as above defined is actually obtained by equating to 0 a factor which appears under a negative index in the expression of  $\frac{dp}{dy}$  or  $\frac{d}{dx} \left( \frac{1}{p} \right)$  it may be considered to belong to the envelope species of singular solutions. In other cases it is deducible from the complete primitive by regarding  $c$  as a constant of multiple value,—its particular values being either 1st dependent in some way on the value of  $x$ , or 2ndly independent of  $x$ , but still such as to render the property a singular one.*

We may add that there exist cases in which the characters of different species of solutions seem to be blended together. Thus  $\frac{dp}{dy}$  may admit of both a finite and an infinite value, indicating a duplex genesis of the solution from the complete primitive. It may also happen that the assumption of an infinite value by  $\frac{dp}{dy}$  may be attributed, indifferently, either to a negative index or to a logarithm. And then it should be inquired whether or not the solution is of the envelope species, but marked with some peculiarity arising from a breach of continuity in the mode of its derivation from the complete primitive.

The following examples are intended to elucidate particular points either of theory or of method.

Ex. 1. Given  $(1 + x^2) \left( \frac{dy}{dx} \right)^2 - 2xy \frac{dy}{dx} + y^2 - 1 = 0.$

This equation, first discussed in Brooke Taylor's *Methodus Incrementorum*, is remarkable as having afforded the earliest instance of the actual deduction of a singular solution from a differential equation (Lagrange, *Calcul des Fonctions*, p. 276). We shall first explain Taylor's procedure, and afterwards apply the above general Theorem.

Taylor differentiates the equation, and finding

$$\left\{ 2(1+x^2) \frac{dy}{dx} - 2xy \right\} \frac{d^2y}{dx^2} = 0,$$

resolves this into the two equations

$$(1+x^2) \frac{dy}{dx} - xy = 0, \quad \frac{d^2y}{dx^2} = 0 \dots\dots\dots (1).$$

The second of these gives  $y = ax + b$ , which satisfies the differential equation provided that  $b = \sqrt{1-a^2}$ . Thus the complete primitive is

$$y = ax + \sqrt{1-a^2}.$$

The first equation of (1) gives, on eliminating  $\frac{dy}{dx}$  by means of the differential equation,

$$y^2 = x^2 + 1,$$

and this he terms the singular solution (*singularis quædam solutio problematis*).

To apply to this example the general method, we find

$$p = \frac{xy \pm \sqrt{(x^2 - y^2 + 1)}}{x^2 + 1}.$$

Hence, 
$$\frac{dp}{dy} = \frac{1}{x^2 + 1} \left\{ x \mp \frac{y}{\sqrt{(x^2 - y^2 + 1)}} \right\}.$$

Introducing the condition  $\frac{dp}{dy} = \infty$ , we should *apparently* have the equations

$$x^2 - y^2 + 1 = 0,$$

$$x^2 + 1 = 0,$$

but of the second of these, as it does not involve  $y$  in its expression, no account is to be taken. The first making  $\frac{dp}{dy}$  infinite whether the upper or the lower sign be taken, and satisfying the differential equation, is a singular solution. Again, as also it is derived from the vanishing of a function under a negative index, it belongs to the envelope species.

We may add that it might be found but less readily from the condition  $\frac{d}{dx} \left( \frac{1}{p} \right) = \infty$ .

The following example is intended to illustrate the use of the latter condition.

Ex. 2. Given  $\frac{dy}{dx} = x^{-n}$ .

Hence, since  $p = x^{-n}$ , the condition  $\frac{dp}{dy} = \infty$  cannot be satisfied.

The condition  $\frac{d}{dx} \left( \frac{1}{p} \right) = \infty$  gives

$$nx^{n-1} = \infty,$$

and this is satisfied by  $x = 0$  if  $n$  be less than 1, but is not satisfied by  $x = 0$  if  $n$  be equal to or greater than 1.

Now the differential equation is satisfied by  $x = 0$ , whatever positive value we give to  $n$ , as may be seen by expressing it in the form  $\frac{dx}{dy} = x^n$ . We conclude therefore that  $x = 0$  is a singular solution of the proposed equation if  $n$  be positive and less than 1, but a particular integral if  $n$  be equal to or greater than 1. We infer too that the solution, when singular, belongs to the envelope species.

In verification, it may be observed that, if  $n$  be not equal to 1, the complete primitive is

$$y = \frac{x^{1-n}}{1-n} + c,$$

or

$$x = \{(1-n)(y-c)\}^{\frac{1}{1-n}}.$$

Now if  $n$  is less than 1, the index in the second member is positive, and we cannot have  $x = 0$  unless the quantity under

the index be made equal to 0. But this would give  $c = y$ , Hence,  $x = 0$  is a singular solution.

If  $n$  be greater than 1, the index in the second member being negative we cannot have  $x = 0$  unless the quantity under the index becomes infinite. But this it does if  $c$  is infinite. Here then  $x = 0$  is a particular integral.

If  $n$  be equal to 1, the complete primitive is

$$x = ce^y,$$

and this is reduced to  $x = 0$  by the assumption  $c = 0$ . Here then also  $x = 0$  is a particular integral.

The following example is intended to illustrate a class of problems in which  $\frac{dp}{dy}$  admits of both a finite and an infinite value.

Ex. 3. Given  $p^2 - 2xy^{\frac{1}{2}}p + 4y^{\frac{3}{2}} = 0$ .

Here we find

$$p = xy^{\frac{1}{2}} \pm \sqrt{(x^2y - 4y^{\frac{3}{2}})} \dots \dots \dots (1).$$

Therefore

$$\frac{dp}{dy} = \frac{1}{2y^{\frac{1}{2}}} \left\{ x \pm \frac{x^2 - 6y^{\frac{1}{2}}}{\sqrt{(x^2 - 4y^{\frac{1}{2}})}} \right\} \dots \dots \dots (2),$$

and this *apparently* becomes infinite when  $y = 0$ , and when  $x^2 - 4y^{\frac{1}{2}} = 0$ , i. e. for

$$y = 0, \quad y = \frac{x^4}{16}.$$

Let us inquire what are the true values of  $\frac{dp}{dy}$ .

1st. If  $y = \frac{x^4}{16}$ , we find, on substitution and reduction,

$$\frac{dp}{dy} = \frac{2}{x^2} \left( x \pm \frac{-x^2}{0} \right),$$

which becomes infinite whichever sign be taken. Hence,  $y = \frac{x^4}{16}$  is a singular solution; and, from the mode of its origin, it is of the envelope species.

2ndly. If  $y = 0$ , the value of  $\frac{dp}{dy}$  in (2) becomes infinite if the upper sign be taken, but assumes the ambiguous form  $\frac{0}{0}$  if the lower sign be taken. To determine its true value, we may expand the fraction  $\frac{x^2 - 6y^{\frac{1}{2}}}{\sqrt{(x^2 - 4y^{\frac{1}{2}})}}$  in ascending powers of  $y^{\frac{1}{2}}$ .

We thus find

$$\frac{dp}{dy} = \frac{1}{2y^{\frac{1}{2}}} \left\{ x \pm \left( x - \frac{4y^{\frac{1}{2}}}{x} + \&c. \right) \right\},$$

which, as before, gives  $\frac{dp}{dy} = \infty$  when, taking the upper sign, we make  $y = 0$ , but on taking the lower sign gives

$$\begin{aligned} \frac{dp}{dy} &= \frac{1}{2y^{\frac{1}{2}}} \left( \frac{4y^{\frac{1}{2}}}{x} + \&c. \right) \\ &= \frac{2}{x} + \text{terms containing positive powers of } y. \end{aligned}$$

And this expression, on making  $y = 0$ , assumes the value  $\frac{2}{x}$ .

These results lead us to infer that the solution  $y = 0$ , originates in two distinct ways from the primitive, which is in this case  $y = c^2 (x - c)^2$ . It is evident that this is reduced to  $y = 0$ , by either of the assumptions  $c = 0$  and  $c = x$ . Hence the solution  $y = 0$  is a particular integral.

At the same time it is to be noted that this solution possesses all the geometrical properties of a singular solution. The complete primitive represents an infinite system of parabolas whose axes are parallel to the axis of  $y$ ,—whose vertices all touch the axis of  $x$ , which thus constitutes a branch of their complete envelope,—and of whose parameters each is inversely as the square of the distance of the corresponding

vertex from the origin of co-ordinates. The nearer any particular vertex is to the origin, the more does the curve to which it belongs approach to a straight line; and the curve, if we may continue thus to speak, whose vertex is at the origin coincides with the axis of  $x$  which is the envelope of the series. It might in a certain real sense be said that the particular and the general are here united.

The following example shews, though by no means in the most extreme case, how slight may be the difference between a singular solution and a particular integral.

Ex. 4. Given  $x \frac{dy}{dx} = y (\log x + \log y - 1)$ .

Representing  $\frac{dy}{dx}$  by  $p$ , we have

$$p = \frac{y (\log x + \log y - 1)}{x};$$

therefore 
$$\frac{dp}{dy} = \frac{\log x + \log y}{x},$$

and this becomes infinite, 1st, if  $y = 0$ , 2ndly, if  $y = \infty$ , 3rdly, if  $x = 0$ .

The first only of these satisfies the differential equation, the assumption  $y = 0$  reducing the indeterminate function  $y \log y$  in the second member to 0 (Todhunter's *Differential Calculus*, Art. 158). We conclude, that  $y = 0$  is a singular solution, but from the nature of its origin not of the envelope species.

Now the complete primitive is  $y = \frac{e^{cx}}{x}$ , and, judging from this, it might at first sight seem as if  $y = 0$  were a particular integral corresponding to  $c = -\infty$ . We remark however that the primitive is not reduced to  $y = 0$ , by the assumption  $c = -\infty$ , unless  $x$  be positive. If  $x$  is negative we must make  $c = +\infty$  to effect that reduction. In fact, the value of  $c$  which reduces the complete primitive to the form  $y = 0$ , though independent of  $x$  in all other respects, is dependent upon  $x$  for

its sign, which must always be opposite to the sign of  $x$ . And this connexion, slight as it is, determines the character of the solution.

The following example illustrates a mode of procedure which may be adopted when  $\frac{dp}{dy}$  presents itself in the ambiguous form  $\frac{0}{0}$ , while the differential equation cannot readily be solved with respect to  $p$ .

Ex. 5. Given  $p^3 - 4xyp + 8y^2 = 0$ .

Differentiating with respect to  $y$  and  $p$ , we find

$$\frac{dp}{dy} = \frac{4xp - 16y}{3p^2 - 4xy} \dots\dots\dots(1).$$

Equating to 0 the denominator, we have  $p = \frac{2x^{\frac{1}{2}}y^{\frac{1}{2}}}{\sqrt{3}}$ , and, substituting this value in the differential equation, we obtain a result resolvable into the following equations, viz.

$$y = \frac{4}{27} x^3, \quad y = 0 \dots\dots\dots(2),$$

either of which satisfies the differential equation. On substitution in (1), the former of these values of  $y$  makes  $\frac{dp}{dy}$  infinite, and is evidently a singular solution. The latter value of  $y$  reduces  $\frac{dp}{dy}$  to the form  $\frac{0}{0}$ .

To determine the real value or values of  $\frac{dp}{dy}$  when  $y = 0$ , we must obtain from the differential equation, regarded as a cubic with respect to  $p$ , the three expressions for that quantity in ascending powers of  $y$ , substitute them in the second member of (1), and then after reduction make  $y = 0$ .

It will somewhat simplify the process if we transform the expressions by assuming  $p = 2ty^{\frac{1}{2}}$ . We shall have

$$\frac{dp}{dy} = \frac{2xt - 4y^{\frac{1}{2}}}{3t^2y^{\frac{1}{2}} - xy^{\frac{1}{2}}} \dots\dots\dots(3),$$

while the differential equation will become

$$t^3 - xt + y^{\frac{1}{2}} = 0 \dots\dots\dots (4),$$

which, expressed in the form

$$t = \frac{y^{\frac{1}{2}}}{x} + \frac{t^3}{x},$$

gives, by Lagrange's theorem,

$$t = \frac{y^{\frac{1}{2}}}{x} + \frac{y^{\frac{3}{2}}}{x^4} + \&c.$$

Substituting in (3), and retaining those terms only which contain the lowest power of  $y$ , we have

$$\frac{dp}{dy} = \frac{-2y^{\frac{1}{2}}}{-xy^{\frac{1}{2}}} = \frac{2}{x}.$$

Such is the value of  $\frac{dp}{dy}$  corresponding to the value of  $t$  which is given by Lagrange's theorem.

That value of  $t$  vanishes with  $y$ . Its other values do not vanish with  $y$ , but approach the limits  $\pm x^{\frac{1}{2}}$  as  $y$  approaches to 0; for if in (4) we make  $y = 0$ , we find 0 and  $\pm x^{\frac{1}{2}}$  for the corresponding values of  $t$ . Now if in (3) we make  $y = 0$ ,  $t = \pm \sqrt{x}$ , we have

$$\frac{dp}{dy} = \infty.$$

From these results combined we infer that  $y = 0$  is a particular integral, possessing the geometrical characters of a singular solution. It originates in fact from the complete primitive  $y = c(x - c)^2$ , either by making  $c = 0$  or  $c = x$ . And that primitive, like the primitive of Ex. 3, represents a system of parabolas enveloped by one of their own number.

Setting out from the primitive we find

$$\frac{d}{dx} \log \frac{dy}{dc} = \frac{1}{x - c} + \frac{1}{x - 3c}.$$

This expression becomes infinite when  $c = \frac{x}{3}$  corresponding to the singular solution  $y = \frac{4}{27} x^3$ . It becomes infinite when  $c = x$ , and assumes the value  $\frac{2}{x}$  when  $c = 0$ ,—these cases belonging to the particular integral  $y = 0$ . All these determinations agree with those of  $\frac{dp}{dy}$  obtained from the differential equation.

The following is an example of a special geometrical problem generalized.

Ex. 6. Determine a curve such, that the area intercepted between its tangent and the rectangular co-ordinate axes shall be constant and equal to  $\frac{a^2}{2}$ .

The supposed area is a right-angled triangle whose base and perpendicular, being the intercepts cut off by the tangents from the co-ordinate axes, are expressed by  $x - \frac{y}{p}$ , and  $y - xp$  respectively. We have therefore

$$(y - xp) \left( x - \frac{y}{p} \right) = a^2.$$

Proceeding in the usual way the singular solution will be found to be

$$xy = \frac{a^2}{4},$$

representing an hyperbola, while the complete primitive represents the series of tangents by whose successive intersection the curve is generated.

To generalize the above problem we might suppose a *functional* relation given between the intercepts. The differential equation would assume the form

$$y - xp = f \left( x - \frac{y}{p} \right).$$

Its complete primitive would always be determinable by the method of Art. 9, Chap. VII. Or, since  $x - \frac{y}{p} = -\frac{y - xp}{p}$ , it is easily seen that the equation is reducible to Clairaut's form

$$y - xp = \phi(p).$$

The singular solution may then be found either as in Chap. VII., or by the direct application of the condition  $\frac{dp}{dy} = \infty$ .

Geometrical problems which are of a truly symmetrical character frequently admit of this kind of generalization.

*Remarks on the foregoing theory.*

12. As the theory of the tests of singular solutions which has been developed in this Chapter differs in many material respects from any that have been given before, it is proper to shew in what its peculiarity consists. To this end it will be necessary briefly to sketch the history of this portion of analysis.

Leibnitz in 1694, Taylor in 1715 (see Ex. 1, Art. 11), and Clairaut in 1734, had in special problems, and Euler in 1756 had in a distinct memoir entitled *Exposition de quelques Paradoxes du Calcul Intégral*, examined, more or less deeply, various questions connected with the singular solutions of differential equations. Taylor in particular had first recognised the distinctive character of such solutions as set forth in their definition. The problem of the deduction of the singular solution from the differential equation seems however to have been first considered in its general form by Laplace. The same problem was subsequently investigated in a different manner by Lagrange, and again in a still different way by Cauchy. The state of the theory up to the present time will be adequately represented by a summary of the results to which these several investigations have led.

1st. Laplace (*Mémoires de l'Académie des Sciences*, 1772), employing the method of expansions, arrived at results which agree, so far as they go, with those of this Chapter. They

apply only to the envelope species of solutions, and the demonstrations of them rest essentially on the hypothesis expressed in (6), Art. 7.

Lagrange, with whom originated a more fundamental idea of the method of the inquiry, was led to the less exact criteria

$$\frac{dp}{dy} = \infty, \quad \frac{dp}{dx} = \infty.$$

(*Calcul des Fonctions*, Leçons XIV—XVII.)

Cauchy, whose method was founded on the study of the cases of failure of certain processes for obtaining the complete primitive in the form of a series, was led to the conclusion that a singular solution must satisfy one of the two following conditions, viz.

$$\frac{dp}{dy} = \frac{0}{0}, \quad \frac{dp}{dy} = \infty,$$

together with a certain further condition, the application of which depends upon a process of integration (Moigno, *Calcul*, Vol. II. p. 435).

Upon these results the following observations may be made,

1st. Although Laplace recognised the necessity of employing in certain cases the condition  $\frac{d}{dx} \left( \frac{1}{p} \right) = \infty$ , for  $\frac{dp}{dy} = \infty$ , subsequent writers who have employed his method seem to have invariably omitted this qualification.

2ndly. The supposed criterion  $\frac{dp}{dx} = \infty$ , introduced by Lagrange, and since very generally adopted, as the proper accompaniment of  $\frac{dp}{dy} = \infty$ , is erroneous. If we should apply it to Ex. 2, Art. 11, viz.  $p = x^{-n}$ , we should be led to the conclusion that  $x = 0$  is a singular solution whenever  $n$  is positive. We have seen however, both from the application of the true test, and by verification from the complete primitive, that  $x = 0$  is a singular solution only when  $n$  is less than 1.

The principle of Lagrange's method was the same as that adopted in the present Chapter, and consisted in expressing  $\frac{dp}{dx}$  and  $\frac{dp}{dy}$  as derived from the differential equation, by means of differential coefficients derived from the complete primitive before the elimination of  $c$ . The fallacy which vitiated his results consisted in assuming that these expressions become infinite in consequence of the appearance of a vanishing factor in their denominators (*Calcul des Fonctions*, pp. 229, 232). Moigno, the expositor of Cauchy's views, also quotes Lagrange's method and results as presented by Caraffa, but without involving any essential variation (*Calcul*, Tom. II. p. 719). Professor De Morgan, in perhaps the latest publication on the subject, adopts Lagrange's results, expressing, however, only a qualified confidence in his method (*Cambridge Philosophical Transactions*, Vol. IX. Pt. II. "On some points of the Integral Calculus"). And he illustrates these results by geometrical considerations which are sufficient to shew that they contain at least a considerable element of truth. Nor should this be thought surprising. For it is plain that Lagrange's condition  $\frac{dp}{dx} = \infty$ , and the true condition  $\frac{d}{dx}\left(\frac{1}{p}\right) = \infty$ , are equivalent, except when the singular solution makes  $p$  assume one of the forms 0 and  $\infty$ . And such cases do exist. Perhaps the peculiar difficulty of this subject has consisted in the faint and shadowy character of the line by which truth and error are separated.

13. Of Cauchy's tests the first, viz.  $\frac{dp}{dy} = \frac{0}{0}$ , may certainly be set aside. Whenever  $\frac{dp}{dy}$  assumes an ambiguous form its true value or values must be determined. This is illustrated in some of the foregoing examples. Professor De Morgan's observations on this subject in the memoir above referred to, are deserving of attention. The final criterion, which is peculiar to Cauchy's theory, seems to be founded upon what we cannot but regard as an unauthorized position as to the meaning of

a singular solution. Thus  $y=0$ , the solution deduced by the criterion  $\frac{dp}{dy} = \infty$  from the differential equation  $p = y \log y$ , is regarded by Cauchy as a particular integral. Now although when  $x$  is real the complete primitive  $\log y = c e^x$  reduces to  $y=0$  by the assumption  $c = -\infty$ , it does not necessarily do so when  $x$  is imaginary. Thus, if  $x = \pi \sqrt{-1}$ , we must make  $c = \infty$ , in order to give  $y=0$ . Cauchy's rule seems indeed to have been designed, contrary to the general spirit of his own writings, to exclude the consideration of imaginary values.

### *Properties of Singular Solutions.*

14. Various properties of singular solutions of the envelope species have been demonstrated. Of these we shall notice the most important.

1st. *An exact differential equation does not admit of a singular solution.*

Let the supposed equation be

$$\frac{d\phi(x, y)}{dx} + \frac{d\phi(x, y)}{dy} \frac{dy}{dx} = 0 \dots \dots \dots (1),$$

and let  $y=f(x)$  be a relation actually satisfying it and assumed to be singular. On this assumption the primitive  $\phi(x, y)=c$  must, on substituting for  $y$  its value  $f(x)$ , determine  $c$  as a function of  $x$  and not a constant. Let  $F(x)$  be the value of  $c$  thus determined, then  $\phi(x, y) = F(x)$ , whence

$$\frac{d\phi(x, y)}{dx} + \frac{d\phi(x, y)}{dy} \frac{dy}{dx} = \frac{dF(x)}{dx} \dots \dots \dots (2),$$

which contradicts (1), since  $\frac{dF(x)}{dx}$  cannot be permanently equal to 0, unless  $F(x)$  is constant.

2ndly. *It follows directly from the above that a singular solution of a differential equation of the first order and degree, makes its integrating factors infinite.*

For let the proposed equation be

$$Mdx + Ndy = 0 \dots \dots \dots (3),$$

and let  $\mu$  be an integrating factor. Then

$$\mu (Mdx + Ndy) = 0 \dots \dots \dots (4),$$

will be an exact differential equation. Hence, a singular solution of (3), while it makes the first member of that equation to vanish, will not make the first member of (4) to vanish. Now comparing these members, this can only be through its making  $\mu$  infinite.

Ex. The equation  $x + y \frac{dy}{dx} = \frac{dy}{dx} \sqrt{(x^2 + y^2 - a^2)}$  has for its singular solution  $x^2 + y^2 = a^2$ . An integrating factor is

$$(x^2 + y^2 - a^2)^{-\frac{1}{2}},$$

and this the singular solution evidently makes infinite. Multiplying the equation by its integrating factor and transposing we have the *exact* differential equation

$$\frac{x + y \frac{dy}{dx}}{\sqrt{(x^2 + y^2 - a^2)}} - \frac{dy}{dx} = 0,$$

or 
$$\frac{d}{dx} \sqrt{(x^2 + y^2 - a^2)} - \frac{dy}{dx} = 0,$$

and this is not satisfied by  $x^2 + y^2 = a^2$ , the singular solution of the unrestricted differential equation.

3rdly. *Even when we are unable to discover its integrating factor, a differential equation may be so prepared as to cease to admit of a given singular solution of the envelope species.*

This proposition is due to Poisson, and the following demonstration, which is purposely given in order to illustrate the nature of the assumption usually employed in the theory of singular solutions, does not essentially differ from his.

Let us represent the singular solution by  $u = 0$ , and transform the differential equation by assuming  $u$  and  $x$  as variables in place of  $y$  and  $x$ . Suppose the new equation reduced to the form

$$p = f(x, u) \dots \dots \dots (5),$$

where  $p$  stands for  $\frac{du}{dx}$ .

This equation is either satisfied or not satisfied by  $u = 0$ .

If it is not satisfied, the preparation in question has already been effected.

If it is satisfied, the second member  $f(x, u)$  contains some positive power of  $u$  as a factor. Assuming that it can be developed in ascending *positive* powers of  $u$  it becomes

$$p = Au^\alpha + Bu^\beta + \dots + \&c.,$$

where  $A, B, C, \&c.$  are functions of  $x$ .

Now, for a singular solution  $\frac{dp}{du} = \infty$ . Hence  $u = 0$  must render

$$A\alpha u^{\alpha-1} + B\beta u^{\beta-1} + \&c. = \infty.$$

But this demands that there should exist at least one negative power of  $u$  in the above development; therefore  $\alpha - 1$ , which is the lowest index, must be negative; therefore  $\alpha$  being already positive must fall between 0 and 1.

Hence we are permitted to express the differential equation in the form

$$p = Qu^\alpha,$$

where  $\alpha$  is a positive fraction, and  $Q$  does not involve  $u$  either as a factor or as a divisor.

Dividing by  $u^\alpha$ , we have

$$u^{-\alpha} \frac{du}{dx} = Q,$$

$$\text{or } \frac{1}{1-\alpha} \frac{d}{dx} u^{1-\alpha} = Q.$$

Now  $u = 0$  makes  $u^{1-\alpha} = 0$ , since  $1 - \alpha$  is positive. Hence the first member of the above equation vanishes, while the second, not containing  $u$  as a factor, does not vanish. In its present form then the equation is no longer satisfied by  $u = 0$ .

We see also that the property of being satisfied by  $u = 0$  has been lost in consequence of a transformation which, exhibiting the singular solution in the form of a distinct algebraic factor of the equation, permitted its rejection. See Art. 1.

It has been shewn in the remarks on Clairaut's equation how, in the process of ascending by differentiation to an equation of a higher order, a somewhat analogous effect is produced, the singular solution seeming to drop aside under changed conditions.

4thly. *Lagrange has noticed that a singular solution will generally make the value of  $\frac{d^2y}{dx^2}$ , as deduced from the differential equation, assume the ambiguous form  $\frac{0}{0}$ .* His demonstration, in the statement of which we shall endeavour to exhibit distinctly the assumptions which it really involves, is substantially as follows. Let the differential equation expressed in a rational and integral form be

$$F(x, y, p) = 0 \dots\dots\dots(1),$$

then differentiating

$$\frac{dF}{dx} dx + \frac{dF}{dy} dy + \frac{dF}{dp} dp = 0 \dots\dots\dots(2).$$

Hence 
$$\frac{dp}{dy} = -\frac{dF}{dy} \div \frac{dF}{dp} = \infty \dots\dots\dots(3).$$

Now  $F$  being rational and integral,  $\frac{dF}{dy}$  and  $\frac{dF}{dp}$  are so also, and therefore the above can only become infinite for finite values of  $x, y$ , and  $p$ , by supposing  $\frac{dF}{dp} = 0$ . This reduces (2) to the form

$$\frac{dF}{dx} dx + \frac{dF}{dy} dy = 0 \dots\dots\dots(4).$$

Now, as obtained from the differential equation,

$$\begin{aligned} \frac{d^2y}{dx^2} &= \frac{dp}{dx} + \frac{dp}{dy} \frac{dy}{dx} \\ &= -\frac{\frac{dF}{dx} + \frac{dF}{dy} \frac{dy}{dx}}{\frac{dF}{dp}}, \end{aligned}$$

an expression which the previous results reduce to the form  $\frac{0}{0}$  .

We may remark that the condition  $\frac{dp}{dy} = \infty$  does not involve as a consequence  $dp = \infty$  in (2), so as to affect the legitimacy of the deduction of (4). For  $\frac{dp}{dy} = \infty$  expresses a *conditional* proposition, whose antecedent is : If  $x$  be constant. Now in the deduction of (4)  $x$  is not supposed to be constant.

Lagrange's demonstration is certainly only applicable to the envelope species of singular solutions. Of such solutions it expresses however an interesting property. For the differential equation being geometrically common both to the locus of the singular solution and to the locus of each particular primitive, the ambiguity of value of  $\frac{d^2y}{dx^2}$  at the point of contact shews that that contact is not generally of the second order.

In like manner,  $F(x, y, p)$  still being supposed rational and integral, the equation

$$\frac{dF(x, y, p)}{dp} = 0 \dots\dots\dots (5),$$

shews by the theory of equations that the existence of a singular solution implies in general the existence of a series of points for which two values of  $\frac{dy}{dx}$ , usually different, come to agree, viz. the values of  $\frac{dy}{dx}$  in any particular primitive, and in the singular solution.

15. Mr De Morgan has made the very interesting remark, that when the condition  $\frac{dp}{dy} = \infty$  , or  $\frac{dp}{dx}$  (in strictness  $\frac{d}{dx} \frac{1}{p}$ )  $= \infty$  , does not lead to a *solution* of the differential equation, what it does lead to is the equation of a curve which constitutes the locus of points of infinite curvature (most commonly cusps)

in the system of curves represented by the complete primitive (*Transactions of the Cambridge Philosophical Society*, Vol. IX. Part II.). Geometrical illustrations will be found in the memoir referred to.

## EXERCISES.

1. The complete primitive of a differential equation is  $y + c = \sqrt{(x^2 + y^2 - a^2)}$ , where  $c$  is the arbitrary constant. Shew that the singular solution is  $x^2 + y^2 = a^2$ , and that it may be connected with the primitive by either of the equivalent relations  $c = -y$  and  $c = \sqrt{(a^2 - x^2)}$ .

2. Why is the above singular solution deducible by the application of *either* of the conditions  $\frac{dx}{dc} = 0$ ,  $\frac{dy}{dc} = 0$ ?

3. Expressing the primitive in Ex. 1 in a rational and integral form  $\phi(x, y, c) = 0$ , deduce the singular solution by the application of the condition  $\frac{d\phi}{dc} = 0$ .

4. The complete primitive of a differential equation being  $x - a = (y - c)^2$ , shew that the singular solution is deducible by the application of the condition  $\frac{dx}{dc} = 0$  but not by that of the condition  $\frac{dy}{dc} = 0$ , and explain the circumstance.

5. The differential equation, whose complete primitive is given in Ex. 1, may be exhibited in the form

$$(x^2 - a^2)p^2 - 2xyp - x^2 = 0.$$

Hence also deduce its singular solution and thereby verify the previous result.

6. Form the differential equation whose complete primitive is given in Ex. 4, and shew that the singular solution is deducible by the application of the condition  $\frac{d}{dx} \frac{1}{p} = \infty$  but not

by that of the condition  $\frac{dp}{dy} = \infty$ , and explain this circumstance.

7. Shew that the singular solutions in the last two examples are of the envelope species.

8. The differential equation  $y = px + \frac{m}{p}$  (Ex. 2, Art. 5) has  $y = cx + \frac{m}{c}$  for its complete primitive, and  $y^2 = 4mx$  for its singular solution. Verify in this example the fundamental relation  $\frac{dp}{dy} = \frac{d}{dx} \log \frac{dy}{dc}$ .

9. Deduce both the singular solution and the complete primitive of the differential equation  $y = px + \sqrt{(b^2 + a^2 p^2)}$ , and interpret each, as well as the connexion of the two, geometrically.

10. The following differential equations admit of singular solutions of the envelope species. Deduce them.

$$x^2 p^2 - 2(xy - 2)p + y^2 = 0,$$

$$(y - xp)(mp - n) = mn p,$$

$$y = (x - 1)p - p^2.$$

11. The equation  $(1 - x^2)p + xy - a = 0$  is satisfied by the equation  $y = ax$ . Is this a singular solution or a particular integral?

12. The equation  $y = \frac{xp}{2}$  is satisfied by  $y = 0$ , which also makes  $\frac{d}{dx} \left( \frac{1}{p} \right) = \infty$ . Nevertheless  $y = 0$  is a particular integral. Shew that this conclusion is in accordance with the general theorem (Art. 11).

13. The equation  $p(x^2 - 1) = 2xy \log y$  has a singular solution which is not of the envelope species. Determine it.

14. Determine also the complete primitive in the last example, and shew how the singular solution arises.

15. The equation

$$(p - y)^2 - 2x^3y(p - y) = 4x^3y^2 - 4x^2y^2 \log y$$

is satisfied by  $y = 0$ . Shew that this is a singular solution but not of the envelope species.

16. Find singular solutions of each of the following equations, and determine whether or not they are of the envelope species.

1.  $p^2 + 2px^3 = 4x^2y$ .
2.  $xp^2 - 2yp + 4x = 0$ .
3.  $xp = n \{x^n + (y - x^n) \log (y - x^n)\}$ .

### *Geometrical Applications.*

In solving the following problems, the differential equation being formed, its complete primitive as well as its singular solution is to be found and interpreted.

17. Determine a curve such that the sum of the intercepts made by the tangent on the axes of co-ordinates shall be constant and equal to  $a$ .

18. Determine a curve such that the portion of its tangent intercepted between the axes of  $x$  and  $y$  shall be constant and equal to  $a$ .

19. Find a curve always touched by the same diameter of a circle rolling along a straight line.

20. Find a curve such that the product of the perpendiculars from two fixed points upon a tangent shall be constant. (Euler. See Lagrange, *Calc. des Fonctions*, p. 282.)

(Representing the product by  $k^2$ , and the distance between the given points by  $2m$ , making the axis of  $x$  coincide with the straight line joining them and taking for the origin of co-ordinates the middle point, the differential equation is

$$\frac{\{y - (x + m)p\} \{y - (x - m)p\}}{1 + p^2} = k^2.$$

Its singular solution is

$$y^2 + \frac{k^2 x^2}{k^2 + m^2} = k^2.)$$

21. Deduce also the complete primitive of the above differential equation.

22. If the primitive of a differential equation be expressed in the form  $\phi(x, y, a) = 0$ , the condition  $\frac{dy}{da} = 0$  may be expressed in the form  $\frac{d\phi(x, y, a)}{da} \div \frac{d\phi(x, y, a)}{dy} = 0$ . Art. 4.

Hence it has sometimes been laid down that  $\frac{d\phi(x, y, a)}{dy} = \infty$  will lead to a singular solution. Raabe, in *Crelle's Journal* (*Ueber singuläre integrale*, Tom. 48), points out that this rule may fail if at the same time  $\frac{d\phi(x, y, a)}{da}$  should become infinite. Can it fail in any other case?

23. Exemplify Raabe's observation in the equation

$$x + c - \sqrt{(6cy - 3c^2)} = 0,$$

which is the complete primitive of  $3xp^2 - 6yp + x + 2y = 0$ . At the same time shew that the singular solutions are

$$y - x = 0 \text{ and } 3y + x = 0. \quad (\text{Crelle, } Ib.)$$

24. The complete primitive of a differential equation is

$$(c - x + y)^3 - 3(x + y)(c - x + y)^2 + 1 = 0.$$

Representing its first member, which is rational and integral, by  $\phi$ , the condition  $\frac{d\phi}{dc} = 0$  assumes the form

$$3(c - x + y)(c - 3x - y) = 0.$$

Shew that  $c - x + y = 0$  will not lead to a solution of the differential equation at all, while  $c - 3x - y = 0$  will, and explain this circumstance by a reference to Art. 4.

NOTE. The reader is reminded that in all references to the general conditions  $\frac{dp}{dy} = \infty$  and  $\frac{d}{dx} \left( \frac{1}{p} \right) = \infty$ , the  $\infty$  means simply "infinity" irrespectively of sign. See General Theorem, Art. 11.

## CHAPTER IX.

### ON DIFFERENTIAL EQUATIONS OF AN ORDER HIGHER THAN THE FIRST.

1. THE typical form of a differential equation of the  $n^{\text{th}}$  order is given in Chap. I. Art. 2. We may, by solving it algebraically with respect to its highest differential coefficient, present it in the form

$$\frac{d^n y}{dx^n} = f\left(x, y, \frac{dy}{dx}, \frac{d^2 y}{dx^2}, \dots, \frac{d^{n-1} y}{dx^{n-1}}\right) \dots\dots\dots (1).$$

Its genesis from a complete primitive involving  $n$  arbitrary constants has been explained, Chap. I. Art. 8.

Conversely, the existence of a differential equation of the above type implies the existence of a primitive involving  $n$  arbitrary constants and no more; and a primitive possessing this character is termed complete.

The converse proposition above stated, is one to which various and distinct modes of consideration point, but concerning the rigid proof of which opinion has differed. The view which appears the simplest is the following. If, as in Chap. II. Art. 2, we represent by  $\Delta\phi(x)$  the increment which the function  $\phi(x)$  receives when  $x$  receives the fixed increment  $\Delta x$ , and if we go on to represent by  $\Delta^2\phi(x)$  the increment which the function  $\Delta\phi(x)$  receives when  $x$  again receives the same fixed increment  $\Delta x$ , and so on, then it is evident that the values of  $\Delta\phi(x)$ ,  $\Delta^2\phi(x)$ , &c., are fully determinable if the successive values of the function  $\phi(x)$  in its successive states of increase are known. Thus since

$$\Delta\phi(x) = \phi(x + \Delta x) - \phi(x),$$

we have by definition

$$\begin{aligned} \Delta^2\phi(x) &= \Delta \{ \phi(x + \Delta x) - \phi(x) \} \\ &= \{ \phi(x + 2\Delta x) - \phi(x + \Delta x) \} - \{ \phi(x + \Delta x) - \phi(x) \} \\ &= \phi(x + 2\Delta x) - 2\phi(x + \Delta x) + \phi(x), \end{aligned}$$

and so on. Conversely if

$$\phi(x), \Delta\phi(x), \Delta^2\phi(x), \&c.$$

are given, the successive values of the function  $\phi(x)$ , viz. the values  $\phi(x + \Delta x)$ ,  $\phi(x + 2\Delta x)$ , &c., are thereby made determinate. Geometrically we may represent  $\phi(x)$  by  $y$ , the ordinate of a curve, or of a series of points in the plane  $x, y$ , and therefore functionally connected with the abscissa  $x$ .

Now the view to which reference has been made is that which, 1st, presents the differential equation (1) as the limiting form of the relation expressed by the equation

$$\frac{\Delta^n y}{\Delta x^n} = f\left(x, y, \frac{\Delta y}{\Delta x}, \frac{\Delta^2 y}{\Delta x^2}, \dots, \frac{\Delta^{n-1} y}{\Delta x^{n-1}}\right) \dots\dots\dots (2),$$

$\Delta x$  approaching to 0; 2ndly, constructs the latter equation in geometry (the arithmetical or purely quantitative construction being therein implied) by a series of points on a plane, of which the first  $n$ , viz. those which answer to the co-ordinates  $x, x + \Delta x, \dots x + (n - 1)\Delta x$ , have the corresponding values of  $y$  arbitrary, while for all the rest the values of  $y$  are determined; 3rdly, represents the solution of the differential equation as the curve which the above series of points in their limiting state tend to form. According to this view, the  $n$  arbitrary points in the constructed solution of the equation of differences (2) give rise to one arbitrary point in the limiting curve, accompanied by  $n - 1$  arbitrary values for the first  $n - 1$  differential coefficients of its ordinate. And this mode of consideration appears the simplest, because it assumes no more than the definition itself demands of us when we attempt to realize the geometrical meaning of a differential coefficient as a limit. We may however add that when by the consideration of the limit, the mere existence of a primitive has been established, other considerations would suffice to shew that in its complete form it will involve  $n$  arbitrary constants and no more. The fact that each integration introduces a single constant is a direct indication of the fact. An indirect proof of a more formal character will be found in a memoir by Professor De Morgan (*Transactions of the Cambridge Philosophical Society*, Vol. IX. Pt. II.).

The above theory may be illustrated by the form in which Taylor's Theorem enables us to present the solution of a differential equation of the  $n^{\text{th}}$  order, as will be seen in the following Article.

*Solution by development in a series.*

2. Reducing the proposed equation to the form

$$\frac{d^n y}{dx^n} = f\left(x, y, \frac{dy}{dx}, \dots \frac{d^{n-1}y}{dx^{n-1}}\right) \dots \dots \dots (3),$$

and differentiating with respect to  $x$ , the first member becomes  $\frac{d^{n+1}y}{dx^{n+1}}$ , while the second member will in general involve all the differential coefficients of  $y$  up to  $\frac{d^n y}{dx^n}$ . If for the last we substitute its value given in (3), the equation will assume the form

$$\frac{d^{n+1}y}{dx^{n+1}} = f_1\left(x, y, \frac{dy}{dx}, \dots \frac{d^{n-1}y}{dx^{n-1}}\right) \dots \dots \dots (4).$$

Thus  $\frac{d^{n+1}y}{dx^{n+1}}$  is expressible in the same manner as  $\frac{d^n y}{dx^n}$ , viz. in terms of  $x$ ,  $y$ , and the first  $n - 1$  differential coefficients of  $y$ .

Differentiating (4) and again reducing the second member by means of (3) we have a result of the form

$$\frac{d^{n+2}y}{dx^{n+2}} = f_2\left(x, y, \frac{dy}{dx}, \dots \frac{d^{n-1}y}{dx^{n-1}}\right) \dots \dots \dots (5),$$

and in this form and by the same method all succeeding differential coefficients may be expressed.

Hence reasoning as in Chap. II. Art. 12, we see that supposing  $y$  to be developed in a series of ascending powers of  $x - x_0$ , where  $x_0$  is an assumed arbitrary value of  $x$ , the coefficients of the higher powers of  $x - x_0$  beginning with  $(x - x_0)^n$  will have a *determinate* connexion, established by means of the differential equation, with the coefficients of the inferior powers of  $x - x_0$ . The latter coefficients,  $n$  in number,

beginning with the constant term which corresponds to the index 0, and ending with  $\frac{1}{1 \cdot 2 \cdot 3 \dots (n-1)} \frac{d^{n-1}y}{dx^{n-1}}$ , which is the coefficient of  $(x-x_0)^{n-1}$ , will be perfectly arbitrary in value.

To exhibit the actual form of the development let  $y_0, y_1, \dots, y_{n-1}$  be the arbitrary values assigned to  $y, \frac{dy}{dx}, \dots, \frac{d^{n-1}y}{dx^{n-1}}$  when  $x = x_0$ . Also let  $f, f_1, f_2, \&c.$  represent the values which the second members of the series of equations (3), (4), (5) assume when we make in them  $x = x_0$ ; then

$$y = y_0 + y_1 (x - x_0) + \frac{y_2}{1 \cdot 2} (x - x_0)^2 \dots + \frac{y_{n-1}}{1 \cdot 2 \cdot (n-1)} (x - x_0)^{n-1} \\ + \frac{f}{1 \cdot 2 \dots n} (x - x_0)^n + \frac{f_1}{1 \cdot 2 \dots (n+1)} (x - x_0)^{n+1} \dots \&c. \text{ ad inf. } \dots (6).$$

In this expression the arbitrary values of  $y$  and its  $n-1$  first differential coefficients corresponding to an assumed and *definite* value of  $x$ , viz.  $y_0, y_1, \dots, y_{n-1}$  are the  $n$  arbitrary constants of the solution, the values of  $f, f_1, f_2, \&c.$ , being determinate functions of these, and therefore not involving any arbitrary element.

Any function of arbitrary constants is itself an arbitrary constant, and thus it may be that an equation has *effectively* a smaller number of arbitrary constants than it appears to have from the mere enumeration of its symbols. As a general principle we may affirm, that the number of effective arbitrary constants in the solution of a differential equation while on the one hand equal to the index of the order of the equation, is on the other hand to be measured by the number of conditions which they enable us to satisfy. Systems of conditions to be thus satisfied will indeed vary in form, but there is one system which we may consider as normal and to which all other systems are in fact reducible. It is that which is described above, and which demands that to a given value of  $x$  a given set of simultaneous values of  $y$  and of its differential coefficients up to an order less by 1 than the order of the equation shall correspond. Conversely, the arbitrary constants

of a solution may be said to be *normal*, when they actually represent a simultaneous system of values of  $y$  and its successive differential coefficients up to the number required.

Ex. Given  $\frac{d^2y}{dx^2} = \frac{dy}{dx} + y^2$ . Required an expression for  $y$  in the form of a series such that when  $x = 0$ ,  $y$  and  $\frac{dy}{dx}$  shall assume the respective values of  $c$  and  $c'$ .

Differentiating, we have

$$\begin{aligned}\frac{d^3y}{dx^3} &= \frac{d^2y}{dx^2} + 2y \frac{dy}{dx} \\ &= \frac{dy}{dx} + y^2 + 2y \frac{dy}{dx}, \text{ by the given equation,} \\ &= y^2 + (1 + 2y) \frac{dy}{dx}, \\ \frac{d^4y}{dx^4} &= 2y \frac{dy}{dx} + 2 \left( \frac{dy}{dx} \right)^2 + (1 + 2y) \frac{d^2y}{dx^2} \\ &= y^2 + 2y^3 + (1 + 4y) \frac{dy}{dx} + 2 \left( \frac{dy}{dx} \right)^2,\end{aligned}$$

by similar reduction, and so on. Hence, corresponding to  $x = 0$ , we have the series of values,

$$\begin{aligned}y &= c, \quad \frac{dy}{dx} = c', \quad \frac{d^2y}{dx^2} = c' + c^2, \\ \frac{d^3y}{dx^3} &= c^2 + (1 + 2c) c', \\ \frac{d^4y}{dx^4} &= c^2 + 2c^3 + (1 + 4c) c' + 2c'^2,\end{aligned}$$

and so on. Hence,

$$\begin{aligned}y &= c + c'x + \frac{c^2 + c'}{2}x^2 \\ &+ \frac{c^2 + (1 + 2c) c'}{2 \cdot 3}x^3 + \frac{c^2 + 2c^3 + (1 + 4c) c' + 2c'^2}{2 \cdot 3 \cdot 4}x^4 + \&c.\end{aligned}$$

*Finitely Integrable Forms.*

3. As the difficulty of the finite integration of differential equations increases as their order is more elevated, it becomes important to classify the chief cases in which that difficulty has been overcome.

It will be found that for the most part these cases are characterized by some one or more of the following marks, viz. 1st, Linearity, the coefficients being at the same time either constant or subject to some restriction as to form; 2ndly, Absence of one or more of the variables or their differential coefficients; 3rdly, Homogeneity; 4thly, Expressibility in the form of an exact differential or in a form easily reducible thereto by means of a multiplier.

The subject of linear equations being of primary importance, we shall devote the remainder of this Chapter to its discussion. But as it will be resumed in another part of this work, and in connexion with a higher method, we propose to notice here only the more important general properties of linear equations, and to illustrate them in the solution of equations with constant coefficients.

*Linear Equations.*

4. The type of a linear differential equation of the  $n^{\text{th}}$  order, (Chap. I. Art. 4), is

$$\frac{d^n y}{dx^n} + X_1 \frac{d^{n-1} y}{dx^{n-1}} + X_2 \frac{d^{n-2} y}{dx^{n-2}} \dots + X_n y = X \dots\dots\dots (7),$$

in which the coefficients  $X_1, X_2 \dots X_n$  and the second member  $X$  are either constant quantities or functions of the independent variable  $x$ .

Considering, first, the case in which the second member is 0, the following important proposition may be established.

PROP. If  $y_1, y_2, \dots y_n$  represent  $n$  distinct values of  $y$ , which individually satisfy the linear equation,

$$\frac{d^n y}{dx^n} + X_1 \frac{d^{n-1} y}{dx^{n-1}} + X_2 \frac{d^{n-2} y}{dx^{n-2}} \dots + X_n y = 0 \dots\dots\dots (8),$$

then will the complete value of  $y$  be

$$y = c_1 y_1 + c_2 y_2 \dots + c_n y_n,$$

$c_1, c_2, \dots c_n$  being arbitrary constants. In other words the *complete* value of  $y$  is the sum of  $n$  distinct particular values of  $y$ , each containing an arbitrary constant.

For on substitution of the assumed general value of  $y$  in (8), we have a result which may be arranged in the following form, viz.

$$\left. \begin{aligned} & c_1 \left( \frac{d^n y_1}{dx^n} + X_1 \frac{d^{n-1} y_1}{dx^{n-1}} + X_2 \frac{d^{n-2} y_1}{dx^{n-2}} \dots + X_n y_1 \right) \\ & + c_2 \left( \frac{d^n y_2}{dx^n} + X_1 \frac{d^{n-1} y_2}{dx^{n-1}} + X_2 \frac{d^{n-2} y_2}{dx^{n-2}} \dots + X_n y_2 \right) \\ & \dots \dots \dots \\ & + c_n \left( \frac{d^n y_n}{dx^n} + X_1 \frac{d^{n-1} y_n}{dx^{n-1}} + X_2 \frac{d^{n-2} y_n}{dx^{n-2}} \dots + X_n y_n \right) \end{aligned} \right\} = 0 \dots (9).$$

Now each line in the left-hand member of the above equation is, from the hypothesis as to the values of  $y_1, y_2, \dots y_n$ , equal to 0. Hence the equation (9) reduces to an identity, and the theorem is established.

The problem of the complete solution of a linear equation of the  $n^{\text{th}}$  order whose second member is equal to 0 is, therefore, reduced to that of finding  $n$  distinct particular solutions, each involving an arbitrary constant.

5. PROP. To solve the linear equation with constant coefficients when the second member is 0.

Were the proposed equation of the first order and of the form

$$\frac{dy}{dx} - my = 0,$$

its solution would be

$$y = c e^{mx}.$$

From this result, and from the known constancy of form of the differential coefficients of exponentials, we are led to examine the effect of such a substitution in the equation

$$\frac{d^n y}{dx^n} + a_1 \frac{d^{n-1} y}{dx^{n-1}} + a_2 \frac{d^{n-2} y}{dx^{n-2}} \dots + a_n y = 0 \dots\dots\dots (10).$$

Assuming then  $y = C\epsilon^{mx}$ , and observing that

$$\frac{d^n (C\epsilon^{mx})}{dx^n} = m^n C\epsilon^{mx},$$

we have, on rejection of the common factor  $C\epsilon^{mx}$ , the equation

$$m^n + a_1 m^{n-1} + a_2 m^{n-2} \dots + a_n = 0 \dots\dots\dots (11),$$

the different roots of which determine the different values of  $m$  which make  $y = C\epsilon^{mx}$  a solution of the equation given.

When those roots are real and unequal, we have, therefore, on representing them by  $m_1, m_2, \dots m_n$ , the system of  $n$  particular solutions,

$$y = C_1 \epsilon^{m_1 x}, y = C_2 \epsilon^{m_2 x}, \dots y = C_n \epsilon^{m_n x} \dots\dots\dots (12),$$

from which by the foregoing theorem we may construct the general solution,

$$y = C_1 \epsilon^{m_1 x} + C_2 \epsilon^{m_2 x} \dots + C_n \epsilon^{m_n x} \dots\dots\dots (13).$$

The equation (11) by which the values of  $m$  are determined is usually called the auxiliary equation.

Ex. Given  $\frac{d^2 y}{dx^2} - 3 \frac{dy}{dx} + 2y = 0$ .

Here, assuming  $y = C\epsilon^{mx}$ , we obtain as the auxiliary equation

$$m^2 - 3m + 2 = 0.$$

Whence the values of  $m$  are 1 and 2. The corresponding particular integrals are  $y = C_1 \epsilon^x$ , and  $y = C_2 \epsilon^{2x}$ , and the complete primitive is

$$y = C_1 \epsilon^x + C_2 \epsilon^{2x}.$$

6. If among the roots, still supposed unequal, imaginary pairs present themselves, the above solution, though formally correct, needs transformation. Let  $a \pm b\sqrt{-1}$  represent one of these pairs, then will the second member of (13) contain a corresponding pair of terms of the form

$$C\epsilon^{(a+b\sqrt{-1})x} + C'\epsilon^{(a-b\sqrt{-1})x},$$

which we may reduce as follows,

$$\begin{aligned} & C\epsilon^{ax+bx\sqrt{-1}} + C'\epsilon^{ax-bx\sqrt{-1}} \\ &= C\epsilon^{ax}(\cos bx + \sqrt{-1}\sin bx) + C'\epsilon^{ax}(\cos bx - \sqrt{-1}\sin bx) \\ &= (C + C')\epsilon^{ax}\cos bx + (C - C')\sqrt{-1}\epsilon^{ax}\sin bx, \end{aligned}$$

or, replacing  $C + C'$  and  $(C - C')\sqrt{-1}$  by new arbitrary constants  $A$  and  $B$ ,

$$A\epsilon^{ax}\cos bx + B\epsilon^{ax}\sin bx \dots\dots\dots(14).$$

Ex. Given  $\frac{d^2y}{dx^2} - 4\frac{dy}{dx} + 13y = 0$ .

Assuming  $y = C\epsilon^{mx}$ , the auxiliary equation is

$$m^2 - 4m + 13 = 0,$$

whence  $m = 2 \pm 3\sqrt{-1}$ . The complete solution therefore is

$$y = A\epsilon^{2x}\cos 3x + B\epsilon^{2x}\sin 3x.$$

7. Lastly, let the auxiliary equation have equal roots whether real or imaginary, e.g. suppose  $m_2 = m_1$ . Then in the general solution (13) the terms  $C_1\epsilon^{m_1x} + C_2\epsilon^{m_2x}$  reduce to a single term  $(C_1 + C_2)\epsilon^{m_1x}$ , and the number of arbitrary constants is effectively diminished, since  $C_1 + C_2$  is only equivalent to a single one. Here then the form (13) ceases to be general.

To deduce the general solution when  $m_2 = m_1$  let us begin by supposing  $m_2$  to differ from  $m_1$  by a finite quantity  $h$ , and

examine the limit to which the terms of the solution, then really general, approach as  $h$  approaches to 0. Now

$$\begin{aligned} C_1 \epsilon^{m_1 x} + C_2 \epsilon^{(m_1+h)x} &= \epsilon^{m_1 x} (C_1 + C_2 \epsilon^{hx}) \\ &= \epsilon^{m_1 x} \left( C_1 + C_2 + C_2 hx + C_2 \frac{h^2 x^2}{1 \cdot 2} \dots \right) \\ &= \epsilon^{m_1 x} \left( A + Bx + Bh \frac{x^2}{1 \cdot 2} + \&c. \right); \end{aligned}$$

on replacing  $C_1 + C_2$  and  $C_2 h$  by  $A$  and  $B$ , new arbitrary constants. This change it is permitted to make, however small  $h$  may be, provided that it is not equal to 0. The limit to which the last member of the above equation approaches as  $h$  approaches to 0 is

$$\epsilon^{m_1 x} (A + Bx).$$

This then is the form which must replace  $C_1 \epsilon^{m_1 x} + C_2 \epsilon^{m_2 x}$  in the general solution.

Suppose next that there exist three equal roots  $m_1, m_2, m_3$ .

Then the terms  $C_1 \epsilon^{m_1 x} + C_2 \epsilon^{m_2 x} + C_3 \epsilon^{m_3 x}$  being replaced by

$$\epsilon^{m_1 x} (A + Bx) + C_3 \epsilon^{m_3 x},$$

make  $m_3 = m_1 + k$ . The above expression becomes

$$\begin{aligned} &\epsilon^{m_1 x} (A + Bx + C_3 \epsilon^{kx}) \\ &= \epsilon^{m_1 x} \left\{ A + C_3 + (B + C_3 k) x + C_3 \frac{k^2}{1 \cdot 2} x^2 + C_3 \frac{k^3}{1 \cdot 2 \cdot 3} x^3 + \&c. \right\} \\ &= \epsilon^{m_1 x} \left( A' + B'x + C'x^2 + \frac{C'k}{3} x^3 + \&c. \right) \dots\dots\dots (15), \end{aligned}$$

on making

$$A + C_3 = A', \quad B + C_3 k = B', \quad \frac{C_3 k^2}{1 \cdot 2} = C'.$$

Here  $A', B', C'$  being functions of the arbitrary constants  $A, B, C$  provided that  $k$  is not actually 0, may themselves be regarded as arbitrary constants. If we so consider them in

(15) and then make  $k$  tend to 0, we see that the limiting form of the expression is

$$\epsilon^{m_1 x} (A' + B'x + C'x^2).$$

And in precisely the same way, were there  $r$  roots equal to  $m_1$ , we should have for the corresponding part of the *complete* value of  $y_1$  the expression

$$\epsilon^{m_1 x} (A_1 + A_2 x + A_3 x^2 \dots + A_r x^{r-1}) \dots \dots \dots (16).$$

Thus the difference which the repetition of a particular root  $m_1$  produces is that the coefficient of the exponential  $\epsilon^{m_1 x}$  is no longer an arbitrary constant, but a polynomial of the form  $A_1 + A_2 x + \&c.$ , the number of arbitrary constants involved being equal to the number of times that the supposed root presents itself.

Ex. Given  $\frac{d^3 y}{dx^3} - \frac{d^2 y}{dx^2} - \frac{dy}{dx} + y = 0.$

Here, assuming  $y = C\epsilon^{mx}$ , the auxiliary equation is

$$m^3 - m^2 - m + 1 = 0,$$

the roots of which are  $-1, 1, 1$ . Thus, corresponding to the root  $-1$ , we have in  $y$  the term  $C\epsilon^{-x}$ , while to the two roots  $1$ , we have the term  $(A + Bx)\epsilon^x$ . The complete primitive therefore is

$$y = C\epsilon^{-x} + (A + Bx)\epsilon^x.$$

8. It follows from (16), that if a pair of imaginary roots  $a \pm b\sqrt{-1}$  present itself  $r$  times, the corresponding portion of the complete value of  $y$  will be

$$(C_1 + C_2 x \dots + C_r x^{r-1}) \epsilon^{ax+bx\sqrt{-1}} + (C_1' + C_2' x \dots + C_r' x^{r-1}) \epsilon^{ax-bx\sqrt{-1}},$$

which, substituting for  $\epsilon^{bx\sqrt{-1}}$  and  $\epsilon^{-bx\sqrt{-1}}$  their trigonometrical values and finally making

$$C_1 + C_1' = A_1, \quad (C_1 - C_1') \sqrt{-1} = B_1, \quad \&c.,$$

assumes the form

$$\begin{aligned} (A_1 + A_2 x \dots + A_r x^{r-1}) \epsilon^{ax} \cos bx \\ + (B_1 + B_2 x \dots + B_r x^{r-1}) \epsilon^{ax} \sin bx. \end{aligned}$$

Hence, therefore, the repetition of a pair of imaginary roots  $a \pm b\sqrt{-1}$  changes also the two arbitrary constants of the ordinary real solution into polynomials, each of which involves a number of constants equal to the number of times that the imaginary pair presents itself.

Ex. Given  $\frac{d^4 y}{dx^4} + 2n^2 \frac{d^2 y}{dx^2} + n^4 y = 0$ .

Assuming  $y = C\epsilon^{mx}$ , the auxiliary equation is

$$m^4 + 2n^2 m^2 + n^4 = 0,$$

whence  $m$  has two pairs of roots of the form  $\pm n \sqrt{-1}$ .

For one such pair the form of solution would be

$$y = A \cos nx + B \sin nx.$$

For the actual case it therefore is

$$y = (A_1 + A_2 x) \cos nx + (B_1 + B_2 x) \sin nx.$$

9. The above, which is the ordinary method of investigating the form of the complete solution when the auxiliary equation involves equal roots, rests on the assumption that a law of continuity connects the form of solution when roots are equal with the form of solution when the roots are unequal. Now, though it is perfectly true that such a law does exist, its assumption without proof of that existence must be regarded as opposed to the requirements of a strict logic. In all legitimate applications of the Differential Calculus it is with a limit that we are directly concerned. Here it is with something which exists, and which admits of being determined independently of the notion of a limit.

Thus if we take as an example  $\frac{d^2 y}{dx^2} - 2 \frac{dy}{dx} + y = 0$ , in which the auxiliary equation  $m^2 - 2m + 1 = 0$  shews that the values of  $m$  are each equal to 1, we are entitled to assume as a particular solution

$$y = C\epsilon^x.$$

Let us now substitute this value of  $y$  in the given equation regarding  $C$  as variable, and inquire whether it admits of any more general determination than it has received above. On substitution we find simply

$$\frac{d^2 C}{dx^2} = 0,$$

whence  $C = A + Bx$ . Thus while the correctness of the solution furnished by the assumption of continuity is established, it is made manifest that this assumption is not indispensable.

We shall endeavour to establish upon other grounds the theory of these cases of failure in a future Chapter. Meanwhile it may be desirable to shew that the form (16) actually satisfies the differential equation when  $r$  values of  $m$  are equal.

In the given equation assume

$$y = C\epsilon^{mx}x^s,$$

$s$  being an integer less than  $r$ . From the theorem for  $\frac{d^m(uv)}{dx^m}$  it easily follows that the result will be of the form

$$\epsilon^{mx} \left\{ f(m) x^s + f'(m) s x^{s-1} + f''(m) \frac{s(s-1)}{1 \cdot 2} x^{s-2} + \dots + f^{(s)}(m) \right\} = 0,$$

in which  $f(m)$  represents the first member of (11). But that equation having by hypothesis  $r$  equal roots, we know by the theory of equations that

$$f(m) = 0, \quad f'(m) = 0, \dots \quad f^{(s)}(m) = 0,$$

are simultaneously true. Thus the differential equation is satisfied. And being satisfied for the particular value of  $y$  in question it is satisfied by (16), which is the sum of all such values.

10. The results of the previous investigation may be summed up in the following rule.

**RULE.** *The coefficients being constant and the second member 0, form an auxiliary equation by assuming  $y = Ce^{mx}$ , and determine the values of  $m$ . Then the complete value of  $y$  will be expressed by a series of terms characterized as follows, viz. For each real distinct value of  $m$  there will exist a term  $Ce^{mx}$ ; for each pair of imaginary values  $a \pm b\sqrt{-1}$ , a term*

$$Ae^{ax} \cos bx + Be^{ax} \sin bx ;$$

*each of the coefficients  $A, B, C$  being an arbitrary constant if the corresponding root occur only once, but a polynomial of the  $(r-1)^{\text{th}}$  degree with arbitrary constant coefficients, if the root occur  $r$  times.*

Ex. Given  $\frac{d^5 y}{dx^5} - \frac{d^3 y}{dx^3} - 2\frac{d^2 y}{dx^2} + 2\frac{dy}{dx} = 0.$

Here the auxiliary equation is

$$m^5 - m^3 - 2m^2 + 2m = 0,$$

whence it will be found that the values of  $m$  are

$$0, 1, 1, -1 \pm \sqrt{-1}.$$

The complete primitive therefore is

$$y = C + (C_1 + C_2 x) e^x + C_3 e^{-x} \cos x + C_4 e^{-x} \sin x.$$

11. To solve the linear equation with constant coefficients when its second member is not equal to 0.

The usual mode of solution is 1st to determine the complete value of  $y$  on the hypothesis that the second member is 0; 2ndly, to substitute its expression in the given equation regarding the arbitrary constants as variable parameters; 3rdly, to determine those parameters so as to satisfy the equation given.

Supposing the given equation to be of the  $n^{\text{th}}$  degree,  $n$  parameters will be employed. These may evidently be subjected to any  $n-1$  arbitrary conditions. Now that system of conditions which renders the discovery of the remaining relation (involved in the condition that the given differential

equation shall be satisfied) the most easy, is that which demands that the formal expression of the  $n-1$  differential coefficients

$$\frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots \frac{d^{n-1}y}{dx^{n-1}}$$

shall, like the formal expression of  $y$ , be the same in the system in which  $c_1, c_2, \dots c_n$  represent variable parameters, as in the system in which they represent arbitrary constants.

The above method is commonly called the method of the variation of parameters. It is, as we shall hereafter see, far from being the easiest mode of solving the class of equations under consideration; but it is interesting as being probably the first general method discovered, and still more so from its containing an application of a principle successfully employed in higher problems.

Ex. Given  $\frac{d^2y}{dx^2} + n^2y = \cos ax$ .

Were the second member 0, the solution would be

$$y = c_1 \cos nx + c_2 \sin nx \dots \dots \dots (a).$$

Assume this then to be the form of the solution of the equation given,  $c_1, c_2$  being variable parameters, but such that  $\frac{dy}{dx}$  shall also retain the same form as if they were constant, viz.

$$\frac{dy}{dx} = -c_1 n \sin nx + c_2 n \cos nx \dots \dots \dots (b).$$

Now the unconditional value of  $\frac{dy}{dx}$  derived from (a) is

$$\frac{dy}{dx} = -c_1 n \sin nx + c_2 n \cos nx + \cos nx \frac{dc_1}{dx} + \sin nx \frac{dc_2}{dx},$$

which reduces to the foregoing form if we assume

$$\cos nx \frac{dc_1}{dx} + \sin nx \frac{dc_2}{dx} = 0 \dots \dots \dots (c).$$

This then is the condition which must accompany (a).

Now differentiating (b) and regarding  $c_1, c_2$  as variable, we have

$$\frac{d^2 y}{dx^2} = -c_1 n^2 \cos nx - c_2 n^2 \sin nx - n \sin nx \frac{dc_1}{dx} + n \cos nx \frac{dc_2}{dx}.$$

Substituting the above values of  $y$  and  $\frac{d^2 y}{dx^2}$  in the given equation, we have

$$-n \sin nx \frac{dc_1}{dx} + n \cos nx \frac{dc_2}{dx} = \cos ax \dots \dots \dots (d),$$

and this equation, in combination with (c), gives

$$\frac{dc_1}{dx} = -\frac{1}{n} \cos ax \sin nx, \quad \frac{dc_2}{dx} = \frac{1}{n} \cos ax \cos nx,$$

whence 
$$c_1 = \frac{1}{2n} \left\{ \frac{\cos (n+a)x}{n+a} + \frac{\cos (n-a)x}{n-a} \right\} + C_1,$$

$$c_2 = \frac{1}{2n} \left\{ \frac{\sin (n+a)x}{n+a} + \frac{\sin (n-a)x}{n-a} \right\} + C_2.$$

Lastly, substituting these values in (a) and reducing, we have

$$y = \frac{\cos ax}{n^2 - a^2} + C_1 \cos nx + C_2 \sin nx \dots \dots \dots (e).$$

This solution fails if  $n = a$ . But giving to (e) the form

$$y = \frac{\cos ax - \cos nx}{n^2 - a^2} + C_1' \cos nx + C_2 \sin nx,$$

and regarding the first term as a vanishing fraction when  $n = a$ , we find

$$y = \frac{x \sin nx}{2n} + C_1' \cos nx + C_2 \sin nx.$$

Or we might proceed thus. Differentiating twice the equation

$$\frac{d^2 y}{dx^2} + n^2 y = \cos nx,$$

we get

$$\frac{d^4 y}{dx^4} + n^2 \frac{d^2 y}{dx^2} = -n^2 \cos nx.$$

Hence eliminating  $\cos nx$

$$\frac{d^4 y}{dx^4} + 2n^2 \frac{d^2 y}{dx^2} + n^4 y = 0,$$

an equation whose complete solution is

$$y = (A + Bx) \cos nx + (C + Dx) \sin nx.$$

Substituting this in the given equation we find  $B = 0$ ,  $D = \frac{1}{2n}$ , whence

$$y = A \cos nx + \left(C + \frac{x}{2n}\right) \sin nx,$$

which agrees with the previous solution.

The latter method, which is general, consists in forming a new equation of a higher order, but with its second member free from that term which is the cause of failure. As by the elevation of the order of the equation superfluous constants are introduced, the relations which connect them must be found by substitution of the result in the given equation.

12. To the class of linear equations with constant coefficients all equations of the form

$$(a+bx)^n \frac{d^n y}{dx^n} + A(a+bx)^{n-1} \frac{d^{n-1} y}{dx^{n-1}} + B(a+bx)^{n-2} \frac{d^{n-2} y}{dx^{n-2}}; \dots + Ly = X,$$

$A, B, \dots L$  being constant and  $X$  a function of  $x$ , may be reduced. It suffices to change the independent variable by assuming  $a + bx = \epsilon^t$ .

Ex. Given  $(a + bx)^2 \frac{d^2 y}{dx^2} + b(a + bx) \frac{dy}{dx} + n^2 y = 0.$

Assuming  $a + bx = \epsilon^t$ , we find

$$\frac{dy}{dx} = b\epsilon^{-t} \frac{dy}{dt},$$

$$\frac{d^2 y}{dx^2} = b^2 \epsilon^{-2t} \left( \frac{d^2 y}{dt^2} - \frac{dy}{dt} \right).$$

Hence, by substitution in the given equation, we have

$$b^2 \frac{d^2 y}{dt^2} + n^2 y = 0,$$

the solution of which is

$$y = C \cos \frac{nt}{b} + C' \sin \frac{nt}{b},$$

in which it only remains to substitute for  $t$  its value  $\log(a+bx)$ .

13. Beside the properties upon which the above methods are founded, linear equations possess many others, of which we shall notice the most important. We suppose, as before,  $y$  to be the dependent,  $x$  the independent variable.

1st. The complete value of  $y$  when the linear equation has a second member  $X$  will be found by adding to any particular value of  $y$  that complementary function which would express its complete value were the second member 0.

Representing the linear equation in the form (7), let  $y_1$  be the particular value of  $y$  which satisfies it,  $Y$  the complete value which would satisfy it were the second member 0; and assume  $y = y_1 + Y$ . The equation then becomes

$$\left. \begin{aligned} & \frac{d^n y_1}{dx^n} + X_1 \frac{d^{n-1} y_1}{dx^{n-1}} \dots + X_n y_1 \\ & + \frac{d^n Y}{dx^n} + X_1 \frac{d^{n-1} Y}{dx^{n-1}} \dots + X_n Y \end{aligned} \right\} = X \dots \dots (17),$$

and this becomes an identity, the first line of its left-hand member being by hypothesis equal to  $X$ , and the second line equal to 0.

Ex. Thus a particular integral of the equation

$$\frac{d^2 y}{dx^2} - a^2 y = x + 1$$

being  $y = -\frac{x+1}{a^2}$ , its complete integral is

$$y = C e^{ax} + C' e^{-ax} - \frac{x+1}{a^2}.$$

The above property, which relates to the *generalizing* of a particular solution, is important, because, as we shall hereafter see, a particular solution of a linear equation may often be obtained by a symbolical process which does not involve even the labour of an integration.

2ndly. The order of a linear differential equation may always be depressed by unity if we know a particular value of  $y$  which would satisfy the equation were its second member equal to 0.

It will suffice to demonstrate this property for the equation of the second order

$$\frac{d^2y}{dx^2} + X_1 \frac{dy}{dx} + X_2 y = X \dots\dots\dots (18).$$

Let  $y_1$  be a particular value of  $y$  when  $X=0$ , and assume  $y = y_1 v$ . Substituting, we have

$$\begin{aligned} & \left( \frac{d^2y_1}{dx^2} + X_1 \frac{dy_1}{dx} + X_2 y_1 \right) v \\ & + \left( 2 \frac{dy_1}{dx} + X_1 y_1 \right) \frac{dv}{dx} + y_1 \frac{d^2v}{dx^2} = X, \end{aligned}$$

the first line of which is by hypothesis 0. In the reduced equation let  $\frac{dv}{dx} = u$ , then we have

$$y_1 \frac{du}{dx} + \left( 2 \frac{dy_1}{dx} + X_1 y_1 \right) u = X \dots\dots\dots (19),$$

a linear equation of the first order for determining  $u$ . And this being found, we have

$$v = \int u dx + c.$$

In the particular case in which  $X=0$ , we find from (19)

$$u = \frac{C e^{-\int X_1 dx}}{y_1^2},$$

whence

$$y = y_1 \left( C \int \frac{e^{-\int X_1 dx}}{y_1^2} dx + C_1 \right) \dots\dots\dots (20).$$

3rdly. Linear equations are connected by remarkable analogies with ordinary algebraic equations.

This subject has been investigated chiefly by Libri and Liouville, who have shewn that most of the characteristic properties of algebraic equations have their analogues in linear differential equations.

Thus an algebraic equation can be deprived of its 2nd, 3rd, ...  $r^{\text{th}}$  term by the solution of an algebraic equation of the 1st, 2nd, ...  $(r-1)^{\text{th}}$  degree. A linear differential equation can be deprived of its 2nd, 3rd, ...  $r^{\text{th}}$  term by the solution of another linear differential equation of the 1st, 2nd, ...  $(r-1)^{\text{th}}$  order.

This may be proved by assuming  $y = vy_1$ , and properly determining  $v$  so as to make in the resulting equation  $y_1$  assume the required form.

Again, as from two simultaneous algebraic equations, we can by the process for greatest common measure obtain a depressed equation satisfied only by their common roots, so from two simultaneous linear differential equations we can by a formally equivalent process deduce a new equation of a depressed order satisfied only by their common integrals.

This is best illustrated by example.

Ex. Required the common integrals, if any, of the equations

$$\frac{d^3y}{dx^3} - 3\frac{d^2y}{dx^2} + 4\frac{dy}{dx} - 2y = 0,$$

$$\frac{d^2y}{dx^2} + 5\frac{dy}{dx} - 6y = 0.$$

Differentiating the second equation and then eliminating  $\frac{d^3y}{dx^3}$  and  $\frac{d^2y}{dx^2}$ , we find the depressed equation

$$\frac{dy}{dx} - y = 0.$$

If we differentiate this we shall find that the result is merely an algebraic consequence of the two equations last

written, not an algebraically new equation. Thus the process of reduction cannot be repeated. We have therefore

$$y = C\epsilon^x$$

as the only common integral.

[See the *Supplementary Volume*, Chapter XXII.]

### EXERCISES.

$$1. \quad \frac{d^2y}{dx^2} - 7 \frac{dy}{dx} + 12y = 0.$$

$$2. \quad \frac{d^2y}{dx^2} - 7 \frac{dy}{dx} + 12y = x.$$

$$3. \quad \text{Integrate } \frac{d^4y}{dx^4} - 4 \frac{d^3y}{dx^3} + 6 \frac{d^2y}{dx^2} - 4 \frac{dy}{dx} + y = 0.$$

$$4. \quad \frac{d^4y}{dx^4} + 2 \frac{d^2y}{dx^2} + y = 0.$$

$$5. \quad \frac{d^3y}{dx^3} - 3 \frac{d^2y}{dx^2} + 4y = 0, \text{ it being given that one of the roots of the auxiliary equation, } m^3 - 3m^2 + 4 = 0, \text{ is } -1.$$

$$6. \quad \frac{d^4y}{dx^4} - 2 \frac{d^3y}{dx^3} + 2 \frac{d^2y}{dx^2} - 2 \frac{dy}{dx} + y = 1.$$

$$7. \quad \frac{d^2y}{dx^2} - 2k \frac{dy}{dx} + k^2y = \epsilon^x.$$

8. What form does the solution of the above equation assume when  $k = 1$ ?

$$9. \quad x^2 \frac{d^2y}{dx^2} - x \frac{dy}{dx} = 3y.$$

$$10. \quad (x + a)^2 \frac{d^2y}{dx^2} - 4(x + a) \frac{dy}{dx} + 6y = 0.$$

$$11. \quad \text{Integrate } \frac{d^2y}{dx^2} - 2bx \frac{dy}{dx} + b^2x^2y = 0.$$

12. A particular integral of  $(1-x^2) \frac{d^2y}{dx^2} - x \frac{dy}{dx} - a^2y = 0$  is  $y = Ce^{a \sin^{-1}x}$ , find the complete integral by the method of Art. 13.

13. The form of the general integral might in the above case be inferred from that of the particular one without employing the method of Art. 13. Prove this.

14. It being given that

$$y = A \left( \sin x + \frac{\cos x}{x} \right) + B \left( \cos x - \frac{\sin x}{x} \right)$$

is the complete integral of the equation  $\frac{d^2y}{dx^2} + \left(1 - \frac{2}{x^2}\right)y = 0$ , find the general integral of  $\frac{d^2y}{dx^2} + \left(1 - \frac{2}{x^2}\right)y = x^2$ .

15. Explain on what grounds it is asserted that the complete integral of a differential equation of the  $n^{\text{th}}$  order contains  $n$  arbitrary constants and no more.

16. Mention any circumstances under which it may be advantageous to form, from a proposed differential equation, one of a higher order. In deducing from the solution of the latter that of the former, what kind of limitation must be introduced?

## CHAPTER X.

### EQUATIONS OF AN ORDER HIGHER THAN THE FIRST, CONTINUED.

1. WE have next to consider certain forms of non-linear equations.

Of the following principle frequent use will be made, viz. *When either of the primitive variables is wanting, the order of the equation may be depressed by assuming as a dependent variable the lowest differential coefficient which presents itself in the equation.*

Thus if the equation be of the form

$$F\left(x, \frac{dy}{dx}, \frac{d^2y}{dx^2}\right) = 0 \dots\dots\dots(1),$$

and we assume

$$\frac{dy}{dx} = z \dots\dots\dots(2),$$

we have, on substitution, the differential equation of the first order,

$$F\left(x, z, \frac{dz}{dx}\right) = 0 \dots\dots\dots (3).$$

If, by the integration of this equation,  $z$  can be determined as a function of  $x$  involving an arbitrary constant  $c$ , {suppose  $z = \phi(x, c)$ }, we have from (2)

$$\frac{dy}{dx} = \phi(x, c),$$

whence integrating

$$y = \int \phi(x, c) dx + c'.$$

If the lowest differential coefficient of  $y$  which presents itself be of the second order, the order of the equation can be depressed by 2, and so on.

A similar reduction may be effected when  $x$  is wanting. Thus, if in the equation of the second order

$$F\left(y, \frac{dy}{dx}, \frac{d^2y}{dx^2}\right) = 0 \dots\dots\dots(4),$$

we assume  $\frac{dy}{dx} = p$ , we have

$$\frac{d^2y}{dx^2} = \frac{dp}{dx} = \frac{dp}{dy} \frac{dy}{dx} = p \frac{dp}{dy},$$

by means of which (4) becomes

$$F\left(y, p, p \frac{dp}{dy}\right) = 0 \dots\dots\dots(5).$$

Should we succeed by the integration of this equation of the first order in determining  $p$  as a function of  $y$  and  $c$ , suppose  $p = \phi(y, c)$ , the equation  $\frac{dy}{dx} = p$  will give

$$dx = \frac{dy}{\phi(y, c)},$$

whence

$$x = \int \frac{dy}{\phi(y, c)} + c' \dots\dots\dots(6).$$

Ex. Suppose  $1 + \left(\frac{dy}{dx}\right)^2 + y \frac{d^2y}{dx^2} = 0$ .

Put  $\frac{dy}{dx} = p$ ; thus

$$1 + p^2 + yp \frac{dp}{dy} = 0,$$

therefore

$$\frac{dy}{y} + \frac{p dp}{1 + p^2} = 0,$$

therefore

$$\log y + \log \sqrt{1 + p^2} = \text{constant},$$

therefore  $y \sqrt{(1 + p^2)} = \text{constant} = b,$

therefore  $1 + p^2 = \frac{b^2}{y^2},$

therefore  $\frac{dx}{dy} = \frac{y}{\sqrt{(b^2 - y^2)}},$

therefore  $x = -\sqrt{(b^2 - y^2)} + a,$

where  $a$  is a constant;

thus finally,  $y^2 + (x - a)^2 = b^2.$

2. In close connexion with the above proposition, stand the three following important cases.

CASE I. When but one differential coefficient as well as but one of the primitive variables presents itself in the given equation.

1st. Let the equation be of the form  $\frac{d^n y}{dx^n} = X$ , we have by successive integrations

$$\frac{d^{n-1}y}{dx^{n-1}} = \int X dx + c,$$

$$\frac{d^{n-2}y}{dx^{n-2}} = \iint X dx^2 + cx + c',$$

and finally

$$y = \iiint \dots X dx^n + c_1 x^{n-1} + c_2 x^{n-2} \dots + c_n \dots (7).$$

We shall hereafter shew that the first term in the second member may be replaced by a series of  $n$  single integrals.

2ndly, If the equation be of the form  $\frac{d^n y}{dx^n} = Y$ , it is not generally integrable, but it is so in the case of  $n = 2$ . Thus there being given

$$\frac{d^2 y}{dx^2} = Y,$$

we have

$$2 \frac{dy}{dx} \frac{d^2y}{dx^2} = 2Y \frac{dy}{dx},$$

and integrating

$$\left(\frac{dy}{dx}\right)^2 = 2 \int Y dy + C.$$

Hence

$$\begin{aligned} \frac{dy}{dx} &= (2 \int Y dy + C)^{\frac{1}{2}}, \\ dx &= \frac{dy}{(2 \int Y dy + C)^{\frac{1}{2}}}, \\ x &= \int \frac{dy}{(2 \int Y dy + C)^{\frac{1}{2}}} + C' \dots\dots\dots(8). \end{aligned}$$

As a particular example, let  $\frac{d^2y}{dx^2} = a^2y$ .

Here

$$\begin{aligned} x &= \int \frac{dy}{(2 \int a^2 y dy + C)^{\frac{1}{2}}} + C' \\ &= \int \frac{dy}{(a^2 y^2 + C)^{\frac{1}{2}}} + C' \\ &= \frac{1}{a} \log \{ay + \sqrt{(a^2 y^2 + C)}\} + C'. \end{aligned}$$

CASE II. When the given equation merely expresses a relation between two consecutive differential coefficients.

Suppose the equation reduced to the form

$$\frac{d^n y}{dx^n} = f\left(\frac{d^{n-1} y}{dx^{n-1}}\right) \dots\dots\dots(9),$$

then, assuming  $\frac{d^{n-1} y}{dx^{n-1}} = z$ , we have

$$\frac{dz}{dx} = f(z),$$

whence

$$\begin{aligned} dx &= \frac{dz}{f(z)}, \\ x &= \int \frac{dz}{f(z)} + c \dots\dots\dots(10). \end{aligned}$$

If, after effecting the integration, we can express  $z$  in terms of  $x$  and  $c$ , suppose  $z = \phi(x, c)$  we have finally to integrate

$$\frac{d^{n-1}y}{dx^{n-1}} = \phi(x, c) \dots\dots\dots(11),$$

which belongs to Case I.

But if, after effecting the integration in (10), we cannot algebraically express  $z$  in terms of  $x$  and  $c$ , we may proceed thus.

From  $\frac{d^{n-1}y}{dx^{n-1}} = z$ , we have

$$\frac{d^{n-2}y}{dx^{n-2}} = \int z dx$$

$$= \int \frac{z dz}{f(z)}.$$

$$\frac{d^{n-3}y}{dx^{n-3}} = \int dx \int \frac{z dz}{f(z)}$$

$$= \int \frac{dz}{f(z)} \int \frac{z dz}{f(z)},$$

and finally,

$$y = \int \frac{dz}{f(z)} \int \frac{dz}{f(z)} \dots \int \frac{z dz}{f(z)} \dots\dots\dots(12),$$

the right-hand member indicating the performance of  $n - 1$  successive integrations, each of which introduces an arbitrary constant. If between this equation and (10) we, after integration, eliminate  $z$ , we shall obtain a final relation between  $y$ ,  $x$ , and  $n$  arbitrary constants, which will be the integral sought.

Ex. Given  $a \frac{d^2y}{dx^2} \frac{d^3y}{dx^3} = \sqrt{\left\{1 + \left(\frac{d^2y}{dx^2}\right)^2\right\}}.$

Making  $\frac{d^2y}{dx^2} = z$ , we have  $az \frac{dz}{dx} = \sqrt{(1 + z^2)}$ , whence

$$x = c + a \sqrt{(1 + z^2)} \dots\dots\dots(a).$$

According to the first of the above methods, we should now solve this with respect to  $z$ , and thus obtaining

$$z = \frac{d^2y}{dx^2} = \sqrt{\left\{\left(\frac{x-c}{a}\right)^2 - 1\right\}},$$

find hence

$$y = \iint \sqrt{\left\{\left(\frac{x-c}{a}\right)^2 - 1\right\}} dx^2 + c_1x + c_2 \dots \dots \dots (b),$$

in which it only remains to effect the integrations. According to the second method, we should proceed thus. Since

$$dx = \frac{azdz}{\sqrt{(1+z^2)}}, \text{ we have}$$

$$\begin{aligned} \frac{dy}{dx} &= \int z dx = \int \frac{az^2 dz}{\sqrt{(1+z^2)}} \\ &= \frac{az \sqrt{(1+z^2)}}{2} - \frac{a}{2} \log \{z + \sqrt{(1+z^2)}\} + c', \end{aligned}$$

whence multiplying the second member by  $\frac{azdz}{\sqrt{(1+z^2)}}$  for  $dx$ , and again integrating,

$$\begin{aligned} y &= \frac{a^2 z^3}{6} - \frac{a^2}{2} \sqrt{(1+z^2)} \log \{z + \sqrt{(1+z^2)}\} + \frac{a^2}{2} z \\ &\quad + ac' \sqrt{(1+z^2)} + c'' \dots \dots (c). \end{aligned}$$

The complete primitive now results from the elimination of  $z$  between (a) and (c).

CASE III. When the given equation merely connects two differential coefficients whose orders differ by 2.

Reducing the equation to the form

$$\frac{d^n y}{dx^n} = f\left(\frac{d^{n-2} y}{dx^{n-2}}\right) \dots \dots \dots (13).$$

Let  $\frac{d^{n-2} y}{dx^{n-2}} = z$ , then

$$\frac{d^2 z}{dx^2} = f(z).$$

This form has been considered under Case I.

It gives

$$x = \int \frac{dz}{\{2 \int f(z) dz + C\}^{\frac{1}{2}}} + C'.$$

If from this equation  $z$  can be determined as a function of  $x$ ,  $C$ , and  $C'$ ,—suppose  $z = \phi(x, C, C')$ ,—then

$$\frac{d^{n-2}y}{dx^{n-2}} = \phi(x, C, C'),$$

the integration of which by Case I. will lead to the required integral. If  $z$  cannot be thus determined, we must proceed as under the same circumstances in Case II.

Ex. Given  $a^2 \frac{d^4y}{dx^4} = \frac{d^2y}{dx^2}.$

Proceeding as above, the final integral will be found to be

$$y = c_1 \epsilon^{\frac{x}{a}} + c_2 \epsilon^{\frac{-x}{a}} + c_3 x + c_4.$$

### *Homogeneous Equations.*

3. There exist certain classes of homogeneous equations which admit of having their order depressed by unity.

CLASS I. Equations which, on supposing  $x$  and  $y$  to be each of the degree 1,  $\frac{dy}{dx}$  of the degree 0,  $\frac{d^2y}{dx^2}$  of the degree  $-1$ , &c., become homogeneous in the ordinary sense.

Adopting the notion and the language of infinitesimals, the earlier analysts described the above class of equations somewhat more simply as homogeneous with respect to the primitive variables and their differentials, i.e. with respect to  $x, y, dx, dy, d^2y$ , &c.

All equations of the above class admit of having their order depressed by unity.

For if we assume  $x = \epsilon^\theta$ ,  $y = \epsilon^\theta z$ , we shall find by the usual method for the change of variables,

$$\frac{dy}{dx} = \frac{dz}{d\theta} + z \dots\dots\dots(14),$$

$$\frac{d^2y}{dx^2} = \epsilon^{-\theta} \left( \frac{d^2z}{d\theta^2} + \frac{dz}{d\theta} \right) \dots\dots\dots(15),$$

and so on. Here  $y$  is presented as of the first degree with respect to  $\epsilon^\theta$  which takes the place of  $x$ , while  $\frac{dy}{dx}$  is of the degree 0, and  $\frac{d^2y}{dx^2}$  of the degree  $-1$ , with respect to  $\epsilon^\theta$ . And the law of continuation is obvious. Hence, from the supposed constitution of the given equation, it follows that on substitution of these values the resulting equation will be homogeneous with respect to  $\epsilon^\theta$ , which will therefore divide out and leave an equation involving only  $z$ ,  $\frac{dz}{d\theta}$ ,  $\frac{d^2z}{d\theta^2}$ , &c. That equation will therefore have its order depressed by unity on assuming

$$\frac{dz}{d\theta} = p \dots (\text{Art. 1}).$$

Let us examine the general form of the result for equations of the second order.

Representing the given equations under the form

$$F \left( x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2} \right) = 0 \dots\dots\dots(16),$$

we have, on substitution,

$$F \left\{ \epsilon^\theta, \epsilon^\theta z, \frac{dz}{d\theta} + z, \epsilon^{-\theta} \left( \frac{d^2z}{d\theta^2} + \frac{dz}{d\theta} \right) \right\} = 0 \dots\dots\dots(17),$$

and from this equation, from what has been above said,  $\epsilon^\theta$  will disappear on division by some power of that quantity, e.g.  $\epsilon^{n\theta}$ . But the effect of simply removing a factor is the same as that of simply replacing such factor by unity. Now to replace  $\epsilon^{n\theta}$  by

unity is the same as to replace  $\epsilon^\theta$  by unity, and if we do this simply, i. e. without changing  $\frac{dz}{d\theta}$  and  $\frac{d^2z}{d\theta^2}$ , (17) will become

$$F\left(1, z, \frac{dz}{d\theta} + z, \frac{d^2z}{d\theta^2} + \frac{dz}{d\theta}\right) = 0 \dots\dots\dots (18).$$

Assuming then  $\frac{dz}{d\theta} = u$ , whence  $\frac{d^2z}{d\theta^2} = \frac{du}{d\theta} = u \frac{du}{dz}$ , we have

$$F\left(1, z, u + z, u \frac{du}{dz} + u\right) = 0 \dots\dots\dots (19),$$

an equation of the first order, which by integration gives

$$u = \phi(z, c) \dots\dots\dots (20).$$

Then since  $u = \frac{dz}{d\theta}$ , we have

$$\begin{aligned} d\theta &= \frac{dz}{\phi(z, c)}, \\ \theta &= \int \frac{dz}{\phi(z, c)} + c' \dots\dots\dots (21), \end{aligned}$$

in which, after effecting the integration, it is only necessary to write

$$\theta = \log x, \quad z = \frac{y}{x} \dots\dots\dots (22).$$

The solution of the proposed equation is therefore involved in (20), (21), (22).

Ex. Given  $nx^3 \frac{d^2y}{dx^2} = \left(y - x \frac{dy}{dx}\right)^2$ .

Substituting as above  $x = \epsilon^\theta$ ,  $y = \epsilon^\theta z$ , we find, as the transformed equation,

$$n \left( \frac{d^2z}{d\theta^2} + \frac{dz}{d\theta} \right) = \left( \frac{dz}{d\theta} \right)^2,$$

whence, making  $\frac{dz}{d\theta} = u$ , we have

$$n \left( u \frac{du}{dz} + u \right) = u^2 \dots\dots\dots (a),$$

which resolves itself into the two equations,

$$n \left( \frac{du}{dz} + 1 \right) = u, \quad u = 0.$$

The former gives on integration

$$u = n + C\epsilon^{\frac{z}{n}}.$$

Now  $u = \frac{dz}{d\theta}$ , whence

$$d\theta = \frac{dz}{n + C\epsilon^{\frac{z}{n}}};$$

therefore  $\theta = -\log (n\epsilon^{\frac{z}{n}} + C) + C'$ ,

and now replacing  $\theta$  by  $\log x$ , and  $z$  by  $\frac{y}{x}$ , we have on reduction,

$$y = nx \log \frac{x}{A + Bx} \dots\dots\dots (b),$$

$A$  and  $B$  being arbitrary constants. This is the complete primitive.

The remaining equation  $u = 0$ , or  $\frac{dz}{d\theta} = 0$ , gives  $z = c$ , or  $y = cx$ , and this is the singular solution.

The equation (a) might have been directly deduced from the given equation by the general theorem (19), which indicates that for such deduction it is only necessary to change  $x$  to 1,  $y$  to  $z$ ,  $\frac{dy}{dx}$  to  $u + z$ , and  $\frac{d^2y}{dx^2}$  to  $u \frac{du}{dz} + u$ .

CLASS II. Equations which on regarding  $x$  as of the first degree,  $y$  as of the  $n^{\text{th}}$  degree,  $\frac{dy}{dx}$  of the  $(n-1)^{\text{th}}$  degree,  $\frac{d^2y}{dx^2}$  of the  $(n-2)^{\text{th}}$  degree, &c., are homogeneous.

To effect the proposed reduction assume  $x = \epsilon^\theta$ ,  $y = \epsilon^{n\theta} z$ . The transformed equation will be free from  $\theta$ , and, on assum-

ing  $\frac{dz}{d\theta} = u$ , will degenerate into an equation of a degree lower by unity between  $u$  and  $z$ .

It is easy to establish that, if the given differential equation be

$$F\left(x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}\right) = 0 \dots\dots\dots (23),$$

the reduced equation for determining  $u$  will be

$$F\{1, z, u + nz, u \frac{du}{dz} + (2n - 1)u + n(n - 1)z\} = 0 \dots\dots (24).$$

Suppose that by the solution of this we find

$$u = \phi(z, c) \dots\dots\dots (25),$$

then since

$$u = \frac{dz}{d\theta}, \text{ we have}$$

$$d\theta = \frac{dz}{\phi(z, c)},$$

$$\theta = \int \frac{dz}{\phi(z, c)} + c' \dots\dots\dots (26),$$

in which it only remains to substitute  $\log x$  for  $\theta$ , and  $\frac{y}{x^n}$  for  $z$ .

$$\text{Ex. Given } x^4 \frac{d^2y}{dx^2} = (x^3 + 2xy) \frac{dy}{dx} - 4y^2.$$

This equation proves homogeneous on assuming  $x$  to be of the degree 1,  $y$  of the degree 2,  $\frac{dy}{dx}$  of the degree 1, and  $\frac{d^2y}{dx^2}$  of the degree 0.

Changing then, according to the formula (24),  $x$  into 1,  $y$  into  $z$ ,  $\frac{dy}{dx}$  into  $u + 2z$ , and  $\frac{d^2y}{dx^2}$  into  $u \frac{du}{dz} + 3u + 2z$ , we have

$$u \frac{du}{dz} + 3u + 2z = (1 + 2z)(u + 2z) - 4z^2 \dots\dots\dots (a),$$

which is reducible to

$$u \left( \frac{du}{dz} + 2 - 2z \right) = 0.$$

This is resolvable into two equations, viz.

$$\frac{du}{dz} + 2 - 2z = 0, \quad u = 0 \dots\dots\dots (b).$$

The first gives on integration

$$u = (z - 1)^2 \pm c^2.$$

Hence, since  $\frac{dz}{d\theta} = u$ , we have

$$d\theta = \frac{dz}{(z - 1)^2 \pm c^2},$$

$$\theta = \frac{1}{c} \tan^{-1} \frac{z - 1}{c} + c', \text{ or } \frac{1}{2c} \log \left( \frac{z - 1 - c}{z - 1 + c} \right) + c'.$$

Hence, replacing  $\theta$  by  $\log x$ , and  $z$  by  $\frac{y}{x^2}$ , we have

$$\log x = \frac{1}{c} \tan^{-1} \frac{y - x^2}{cx^2} + c', \text{ or } \frac{1}{2c} \log \frac{y - (1 + c)x^2}{y - (1 - c)x^2} + c',$$

the rational forms of the integral required.

The factor  $u = 0$  in (b) giving  $\frac{dz}{d\theta} = 0$ , or  $z = c$ , leads to the singular solution  $y = cx^2$ .

CLASS III. Equations which are homogeneous with respect to  $y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \&c.$

Properly speaking, this class constitutes a limit to the class just considered. For when  $n$  becomes large, the quantities  $n, n - 1, n - 2$ , the supposed measures of the degrees of  $y, \frac{dy}{dx}, \frac{d^2y}{dx^2}$  approach a ratio of equality.

If we assume  $y = \epsilon^z$ , we have

$$\frac{dy}{dx} = \epsilon^z \frac{dz}{dx} \dots\dots\dots(27),$$

$$\frac{d^2y}{dx^2} = \epsilon^z \left\{ \frac{d^2z}{dx^2} + \left( \frac{dz}{dx} \right)^2 \right\} \dots\dots\dots(28).$$

All these being of the first degree with respect to  $\epsilon^z$ , it follows that after substitution in the proposed equation, that function will disappear on division. Thus, if the given equation be

$$F\left(x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}\right) = 0 \dots\dots\dots(29),$$

the transformed equation will be

$$F\left\{x, 1, \frac{dz}{dx}, \frac{d^2z}{dx^2} + \left(\frac{dz}{dx}\right)^2\right\} = 0 \dots\dots\dots(30),$$

or, on assuming  $\frac{dz}{dx} = u$ ,

$$F\left(x, 1, u, \frac{du}{dx} + u^2\right) = 0 \dots\dots\dots(31).$$

Integrating this equation of the first degree, we have

$$u = \phi(x, c);$$

therefore

$$z = \int \phi(x, c) dx + c' \dots\dots\dots(32),$$

in which it only remains to substitute for  $z$  its value  $\log y$ .

Or we may assume at once  $y = \epsilon^{\int u dx}$ . The transformed equation between  $u$  and  $x$  will be of an order lower by unity than the equation given.

Ex. Given  $ay \frac{d^2y}{dx^2} + b \left(\frac{dy}{dx}\right)^2 = \frac{y \frac{dy}{dx}}{\sqrt{(e^2 + x^2)}}.$

Assuming  $y = \epsilon^{\int u dx}$ , we find

$$a \left(\frac{du}{dx} + u^2\right) = \frac{u}{\sqrt{(e^2 + x^2)}} - bu^2,$$

as would directly result from (29) and (30). Expressed in the form

$$\frac{du}{dx} - \frac{u}{a\sqrt{e^2 + x^2}} = -\left(1 + \frac{b}{a}\right)u^2,$$

this equation is seen to belong to the class discussed in Chap. II. Art. 11.

On comparing the above classes of homogeneous equations we see that Class II. is the most general. It includes Class I. as a subordinate species, and Class III. as a limit.

It is proper to observe that Classes I. and II. are usually treated by a different method from that above employed. Thus, in Class I., it is customary to make the assumptions

$$y = xt, \quad \frac{dy}{dx} = u, \quad \frac{d^2y}{dx^2} = \frac{v}{x}, \quad \frac{d^3y}{dx^3} = \frac{w}{x^2}, \quad \&c.$$

On substitution  $x$  divides out, and there remains an equation involving  $y$  and the new variables  $t, u, v, w, \&c.$ , which may be reduced by successive eliminations to a differential equation between two variables, and of an order lower by unity than the equation given. But this method is far more complicated than the one which we have preferred to employ.

### *Exact Differential Equations.*

4. A differential equation of the form

$$\phi\left(x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots, \frac{d^ny}{dx^n}\right) = 0 \dots\dots(33),$$

is said to be exact if, representing its first member by  $V$ , the expression  $Vdx$  is the exact differential of a function  $U$ , which is therefore necessarily of the form  $\psi\left(x, y, \frac{dy}{dx}, \dots, \frac{d^{n-1}y}{dx^{n-1}}\right)$ .

Thus  $\frac{dy}{dx} \frac{d^2y}{dx^2} - yx^2 \frac{dy}{dx} - xy^2 = 0$  is an exact differential equation, its first member multiplied by  $dx$  being the differential of the function  $\frac{1}{2} \left\{ \left( \frac{dy}{dx} \right)^2 - x^2 y^2 \right\}$ , and the first member itself the differential coefficient of that function.

Hence then a first integral of the above equation will be

$$\left(\frac{dy}{dx}\right)^2 - x^2 y^2 = c.$$

The method of integrating an exact differential equation which we shall illustrate, and which contains an implicit solution of the question whether a proposed equation is exact or not, appears to be primarily due to M. Sarrus (*Liouville*, Tom. XIV. p. 131, note).

Ex. Given  $y + 3x \frac{dy}{dx} + 2y \left(\frac{dy}{dx}\right)^3 + \left(x^2 + 2y^2 \frac{dy}{dx}\right) \frac{d^2 y}{dx^2} = 0.$

Supposing the above an exact differential, we are by definition permitted to write

$$dU = \left\{ y + 3x \frac{dy}{dx} + 2y \left(\frac{dy}{dx}\right)^3 + \left(x^2 + 2y^2 \frac{dy}{dx}\right) \frac{d^2 y}{dx^2} \right\} dx \dots (34).$$

Now a first and obvious condition is that the highest differential coefficient in an exact differential equation, being the one introduced by differentiation, can only present itself in the first degree. This condition is seen to be satisfied.

Representing the highest differential coefficient but one by  $p$ , we can express (34) in the form

$$dU = (y + 3xp + 2yp^3) dx + (x^2 + 2y^2 p) dp.$$

Now let  $U_1$  represent what the integral of the term containing  $dp$  would be were  $p$  the only variable. Then

$$U_1 = x^2 p + y^2 p^2.$$

Assume, then, removing all restriction,

$$U_1 = x^2 \frac{dy}{dx} + y^2 \left(\frac{dy}{dx}\right)^2,$$

whence

$$dU_1 = \left\{ 2x \frac{dy}{dx} + 2y \left(\frac{dy}{dx}\right)^3 + \left(x^2 + 2y^2 \frac{dy}{dx}\right) \frac{d^2 y}{dx^2} \right\} dx.$$

Subtracting this from (34)

$$dU - dU_1 = \left(y + x \frac{dy}{dx}\right) dx \dots \dots \dots (35).$$

We remark that the highest differential coefficient  $\frac{d^2y}{dx^2}$  has now disappeared. We observe too that the next, viz.  $\frac{dy}{dx}$  is involved only in the first degree. This is a consequence of the fact that the proposed differential equation was really exact. For the first member of (35) being the difference of two exact differentials, and therefore itself exact, the second member is so, and its highest differential coefficient is therefore of the first degree. The integration of an exact differential involving  $\frac{d^2y}{dx^2}$  has, in fact, been reduced to that of an exact differential involving only  $\frac{dy}{dx}$  as its highest differential coefficient. And a similar reduction may be effected whatever may be the order of the highest differential coefficient.

The integration of (35) gives

$$U - U_1 = xy,$$

whence

$$U = U_1 + xy = x^2 \frac{dy}{dx} + y^2 \left( \frac{dy}{dx} \right)^2 + xy.$$

A first integral of the given equation is, therefore,

$$x^2 \frac{dy}{dx} + y^2 \left( \frac{dy}{dx} \right)^2 + xy = c \dots \dots \dots (36).$$

The general rule for the integration of an exact differential  $dU$ , involving  $x, y, \frac{dy}{dx}, \dots, \frac{d^n y}{dx^n}$ , is then as follows. *Integrate the term which involves  $\frac{d^n y}{dx^n}$  in the first degree, as if  $\frac{d^{n-1}y}{dx^{n-1}}$  were the only variable, and  $\frac{d^n y}{dx^n} dx$  its differential. Representing the result by  $U_1$ , and removing the restriction,  $dU - dU_1$  will be an exact differential involving only  $x, y, \frac{dy}{dx}, \dots, \frac{d^{n-1}y}{dx^{n-1}}$ . Repeat the process as often as necessary. Then  $U$  will be expressed by the sum of its successively determined portions  $U_1, U_2, U_3$ , &c.*

For the solution of an exact differential equation, it is therefore only needful to equate to  $c$  the integral of the corresponding exact differential as found by the above process.

The failure of that process, through the occurrence of a form in which the highest differential coefficient is not of the first degree, indicates that the proposed function or equation is not 'exact.'

5. There is another mode of proceeding of which it is proper that a brief account should be given.

Representing  $\frac{dy}{dx}$ ,  $\frac{d^2y}{dx^2}$ , ...  $\frac{d^ny}{dx^n}$ , by  $y_1, y_2, \dots, y_n$ , it is easily shewn by the Calculus of Variations, that if  $Vdx$  be an exact differential,  $V$  being a function of  $x, y, y_1, \dots, y_n$ , then identically

$$\frac{dV}{dy} - \left(\frac{d}{dx}\right) \frac{dV}{dy_1} + \left(\frac{d}{dx}\right)^2 \frac{dV}{dy_2} \dots \mp \left(\frac{d}{dx}\right)^n \frac{dV}{dy_n} = 0 \dots\dots\dots (37),$$

where  $\left(\frac{d}{dx}\right)$  indicates that we differentiate with respect to  $x$  regarding  $y, y_1, \dots, y_n$  as functions of  $x$ . This condition was discovered by Euler.

The researches of Sarrus and De Morgan, not based upon the employment of the Calculus of Variations, have shewn, 1st, that the above condition is not only necessary but sufficient. 2ndly, that it constitutes the last of a series of theorems which enable us, when the above condition is satisfied, to reduce  $Vdx$  to an exact differential in *form*, i.e. to express it in the form

$$\frac{dU}{dx} dx + \frac{dU}{dy} dy + \frac{dU}{dy_1} dy_1 \dots + \frac{dU}{dy_{n-1}} dy_{n-1} \dots\dots\dots (38),$$

where  $x, y, y_1, \dots, y_{n-1}$  are regarded as independent. The integration of  $Vdx = 0$  in the form  $U = c$  is thus reduced to the integration of an exact differential of a function of  $n + 1$  independent variables,—a subject to be discussed in Chapter XII. (*Cambridge Transactions*, Vol. IX.)

The condition (37) is singly equivalent to the system of conditions implied in the process of Sarrus. The proof of this equivalence *a posteriori* would, as Bertrand has observed, be complicated. (Liouville, Tom. XIV.)

The solution of the differential equations of orders higher than the first is sometimes effected by means of an integrating factor  $\mu$ , to discover which we might substitute  $\mu V$  for  $V$  in (37), and endeavour to solve the resulting partial differential equation. Even here, however, the process of Sarrus would be preferable.

*Miscellaneous Methods and Examples.*

6. Many forms of equations, besides those above noted, can be integrated by special methods, e. g. by transformations, variation of parameters, reduction to exact differentials, &c. Equations of the classes already considered can also sometimes be integrated by processes more convenient than those above explained.

Ex. 1. Given  $\frac{d^2y}{dx^2} = ax + by$ .

Let  $ax + by = t$ . We find as the result,  $\frac{d^2t}{dx^2} = bt$  a linear equation with constant coefficients.

Ex. 2. Given  $(1 - x^2) \frac{d^2y}{dx^2} - x \frac{dy}{dx} + q^2y = 0$ .

Changing the independent variable by assuming  $\sin^{-1} x = t$ , we find  $\frac{d^2y}{dt^2} + q^2y = 0$ , whence the final solution is

$$y = c_1 \cos (q \sin^{-1} x) + c_2 \sin (q \sin^{-1} x) \dots \dots \dots (39).$$

So too the equation  $(1 + ax^2) \frac{d^2y}{dx^2} + ax \frac{dy}{dx} \pm q^2y = 0$ , is reducible to the form  $\frac{d^2y}{dt^2} \pm q^2y = 0$ , by the assumption

$$\int \frac{dx}{\sqrt{(1 + ax^2)}} = t.$$

Equations involving the arc  $s$ , whether explicitly or implicitly, may be freed from it by differentiation or by change of independent variable.

Ex. 3. Given  $s = ax + by$ .

Differentiating, we have  $\sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}} = a + b \frac{dy}{dx}$ ;

therefore  $\frac{dy}{dx} = \frac{ab \pm \sqrt{(a^2 + b^2 - 1)}}{1 - b^2}$ ,

$$y = \frac{ab \pm \sqrt{(a^2 + b^2 - 1)}}{1 - b^2} x + c.$$

Ex. 4. Given  $\frac{d^2x}{ds^2} = a$ .

Assuming  $x$  as independent variable, we have

$$\begin{aligned} \frac{d^2x}{ds^2} &= \frac{dx}{ds} \frac{d}{dx} \frac{dx}{ds} = \left(\frac{ds}{dx}\right)^{-1} \frac{d}{dx} \left(\frac{ds}{dx}\right)^{-1} \\ &= -\left(\frac{ds}{dx}\right)^{-3} \frac{d^2s}{dx^2} = a. \end{aligned}$$

We might here put for  $\frac{ds}{dx}$  its value  $\sqrt{(1 + p^2)}$ , and so form a differential equation for determining  $p$ . Direct integration, however, gives

$$\left(\frac{ds}{dx}\right)^{-2} = 2ax + c.$$

Whence we find

$$\begin{aligned} \frac{dy}{dx} &= \left(\frac{1}{2ax + c} - 1\right)^{\frac{1}{2}}; \\ y &= \int \left(\frac{1}{2ax + c} - 1\right)^{\frac{1}{2}} dx + c'; \end{aligned}$$

which indicates a cycloid.

7. M. Liouville has shewn how to integrate the general equation  $\frac{d^2y}{dx^2} + f(x) \frac{dy}{dx} + F(y) \left(\frac{dy}{dx}\right)^2 = 0$  (*Journal de Mathématiques*, 1st Series, Tom. VII. p. 134).

Suppressing the last term, the resulting equation

$$\frac{d^2y}{dx^2} + f(x) \frac{dy}{dx} = 0$$

has for a first integral  $\frac{dy}{dx} = C\epsilon^{-\int f(x) dx}$ . Now assume this to be a first integral of the given equation regarding  $C$  as an unknown function of  $y$ , then

$$\begin{aligned}\frac{d^2y}{dx^2} &= \epsilon^{-\int f(x) dx} \left\{ \frac{dC}{dy} \frac{dy}{dx} - Cf(x) \right\} \\ &= \frac{1}{C} \frac{dy}{dx} \left\{ \frac{dC}{dy} \frac{dy}{dx} - Cf(x) \right\} \\ &= \frac{1}{C} \frac{dC}{dy} \left( \frac{dy}{dx} \right)^2 - f(x) \frac{dy}{dx}.\end{aligned}$$

Thus, the given equation becomes

$$\frac{1}{C} \frac{dC}{dy} + F(y) = 0 \dots\dots\dots (40),$$

whence

$$C = A\epsilon^{-\int F(y) dy}.$$

Therefore 
$$\frac{dy}{dx} = A\epsilon^{-\int F(y) dy} \times \epsilon^{-\int f(x) dx};$$

therefore 
$$\int \epsilon^{\int F(y) dy} dy = A \int \epsilon^{-\int f(x) dx} dx + B \dots\dots\dots (41),$$

the complete primitive sought.

8. Jacobi has established that when one of the first integrals of a differential equation of the form  $\frac{d^2y}{dx^2} = f(x, y)$  is known, the complete primitive may be found. The following demonstration of this proposition is due to Liouville (*Journal de Mathématiques*, 1st Series, Tom. XIV. p. 225).

Let the given first integral be  $\frac{dy}{dx} = \phi(x, y, c)$ . Differentiating, we have

$$\frac{d^2y}{dx^2} = \frac{d\phi}{dx} + \frac{d\phi}{dy} \frac{dy}{dx} = \frac{d\phi}{dx} + \phi \frac{d\phi}{dy},$$

$\phi$  standing for  $\phi(x, y, c)$ . Hence, comparing with the given equation,

$$\frac{d\phi}{dx} + \phi \frac{d\phi}{dy} = f(x, y),$$

and differentiating with respect to  $c$ ,

$$\frac{d^2\phi}{dxdc} + \frac{d\phi}{dc} \frac{d\phi}{dy} + \phi \frac{d^2\phi}{dydc} = 0.$$

Now this is precisely the condition which must be satisfied in order that the expression  $\frac{d\phi}{dc} (dy - \phi dx)$  may be an exact differential. Hence, the first integral expressed in the form  $dy - \phi dx = 0$ , is made an exact differential by means of the factor  $\frac{d\phi}{dc}$ . The complete primitive therefore is

$$\int \frac{d\phi}{dc} (dy - \phi dx) = C \dots \dots \dots (42).$$

Some equations of great difficulty connected with the theory of the elliptic functions are reduced to the above case in the memoir referred to.

### *Singular Integrals.*

9. Equations of the higher orders, like those of the first order, sometimes admit of singular integrals, i.e. of integrals not derivable from the ordinary ones without making one or more of their constants variable.

We shall term such integrals singular solutions when they connect only the primitive variables, but singular integrals when they present themselves in the form of differential equations inferior in order to the equation given.

And as the entire theory is involved in the theory of singular first integrals, we shall speak chiefly of these, but with less detail than in the corresponding inquiries of Chap. VIII.

[Additions to the present Chapter are given in the *Supplementary Volume*, Chapter XXIII.]

PROP. Given a first integral with arbitrary constant of a differential equation of the  $n^{\text{th}}$  order, required the corresponding singular integral.

Let the given equation be

$$F(x, y, y_1, y_2 \dots y_n) = 0 \dots \dots \dots (43),$$

where  $y_1$  stands for  $\frac{dy}{dx}$ ,  $y_2$  for  $\frac{d^2y}{dx^2}$ , &c. Suppose the integral given to be expressed in the form

$$y_{n-1} = f(x, y, y_1 \dots y_{n-2}, c) \dots\dots\dots(44),$$

$c$  being an arbitrary constant. Differentiating as if  $c$  were an unknown function of  $x$ ,

$$y_n = \frac{df}{dx} + \frac{df}{dy} y_1 + \frac{df}{dy_1} y_2 \dots + \frac{df}{dy_{n-2}} y_{n-1} + \frac{df}{dc} \frac{dc}{dx}.$$

Now this reduces to the same form, i.e. gives the same expression for  $y_n$  in terms of  $x, y_1 \dots y_{n-1}, c$ , as it would do if  $c$  were constant, provided that we have  $\frac{df}{dc} = 0$ ; and therefore, this condition satisfied, the elimination of  $c$  will still lead to the given differential equation (43).

An integral of the given equation will therefore be found by attributing to  $c$  in the complete first integral (44), such value as will satisfy the condition  $\frac{df}{dc} = 0$ , or, as we may express it,

$$\frac{dy_{n-1}}{dc} = 0 \dots\dots\dots(45).$$

And unless the value of  $c$  thus found is constant, the integral will be singular. The above process amounts to eliminating  $c$  between (44) and (45), so that we have the following rule.

*Given a first integral of a differential equation of the  $n^{\text{th}}$  order, to deduce the corresponding singular integral, we must eliminate  $c$  between the first integral in question and the equation  $\frac{dy_{n-1}}{dc} = 0$ , where  $y_{n-1}$  is the value of  $\frac{d^{n-1}y}{dx^{n-1}}$  expressed in terms of  $x, y \dots \frac{d^{n-2}y}{dx^{n-2}}$ , &c. by means of the given first integral.*

If the proposed first integral is rational and integral in

form, then representing it by  $\phi = 0$ , it suffices to eliminate  $c$  between the equations,

$$\phi = 0, \quad \frac{d\phi}{dc} = 0 \dots \dots \dots (46).$$

It is unnecessary to dwell on the particular cases of exception after what has been said on this subject in Chap. VIII.

Ex. 1. The differential equation

$$y - xy_1 + \frac{x^2}{2} y_2 - (y_1 - xy_2)^2 - y_2^2 = 0,$$

has for a first integral

$$y - \frac{x}{2} (b + y_1) - \frac{(b - y_1)^2}{x^2} - b^2 = 0;$$

required the corresponding singular integral.

Differentiating the first integral with respect to  $b$ , we find

$$\frac{x}{2} + \frac{2(b - y_1)}{x^2} + 2b = 0,$$

whence  $b = \frac{4y_1 - x^3}{4(1 + x^2)}$ , and this value substituted in the given integral, leads to

$$y - \frac{xy_1}{2} - \frac{y_1^2}{x^2} + \frac{(4y_1 - x^3)^2}{16x^2(1 + x^2)} = 0,$$

or, on reduction,

$$16(1 + x^2)y - 8x^3y_1 - 16xy_1 + x^4 - 16y_1^2 = 0.$$

In connexion with this subject, Lagrange has established the following propositions:

1st. Either of the first two integrals of a differential equation of the second order leads to the same singular integral of that equation.

2nd. The complete primitive of a singular integral of a differential equation of the second order will itself be a singular solution of that equation, but a singular solution of a singular integral will in general not be a solution at all of that equation.

The proof of these propositions will afford an exercise for the student.

[See Lagrange's *Leçons sur le Calcul des Fonctions*, *Leçon* 14<sup>me</sup> of the edition of 1806, or *Leçon* 15<sup>me</sup> of the edition of 1808. A note by Poisson on page 239 of the edition of 1808 should be consulted; it relates to the second of the above two propositions. See also Lacroix, *Traité du Calcul Différentiel* ..., Tome II. pp. 382 and 390.]

10. We proceed to inquire how singular integrals may be determined from the differential equation.

Expressing as before the first integral involving an arbitrary constant in the form

$$y_{n-1} = f(x, y, y_1 \dots y_{n-2}, c) \dots\dots\dots(47),$$

we have as the derived equation

$$y_n = \left\{ \frac{df(x, y, y_1 \dots y_{n-2}, c)}{dx} \right\} \dots\dots\dots(48),$$

the brackets in the second member indicating that in effecting the differentiation  $y, y_1, \dots y_{n-2}$ , are to be regarded as functions of  $x$ . The differential equation of the  $n^{\text{th}}$  order is found from (48) by substituting therein, after the differentiation, for  $c$  its value in terms of  $x, y, y_1, \dots y_{n-1}$ , given by (47). The result assumes the form

$$y_n = \phi(x, y, y_1 \dots y_{n-1}) \dots\dots\dots(49).$$

Hence, we have

$$\frac{dy_n}{dy_{n-1}} \text{ in (49)} = \frac{dy_n}{dc} \text{ in (48)} \times \frac{dc}{dy_{n-1}} \text{ in (47)},$$

or, representing  $f(x, y, y_1 \dots y_{n-2}, c)$ , by  $f$ ,

$$\frac{dy_n}{dy_{n-1}} \text{ in (49)} = \left( \frac{d^2 f}{dx dc} \right) \div \frac{df}{dc}.$$

Hence,

$$\frac{dy_n}{dy_{n-1}} = \frac{d}{dx} \log \frac{dy_{n-1}}{dc} \dots\dots\dots(50),$$

provided that the first member be obtained from the differential equation, and the second member from one of its

first integrals involving  $c$  as arbitrary constant. It is to be borne in mind that in effecting the differentiation with respect to  $x$  in the second member, we must regard  $y, y_1, \dots y_{n-2}$  as functions of  $x$ .

Now reasoning as in Chap. VIII. since a singular solution makes  $\frac{dy_{n-1}}{dc} = 0$ , it makes its logarithm, and in general the differential of its logarithm, infinite. Thus we arrive at the following conclusion.

A singular integral of a differential equation of the  $n^{\text{th}}$  order will in general satisfy the condition  $\frac{dy_n}{dy_{n-1}} = \infty$ , and a relation which satisfies both this condition and the differential equation will be a singular integral.

Ex. 2. Applying this method to the equation,

$$y - xy_1 + \frac{x^2}{2} y_2 - (y_1 - xy_2)^2 - y_2^2 = 0,$$

we find, on differentiating with respect to  $y_1$  and  $y_2$  only,

$$- \{x + 2(y_1 - xy_2)\} dy_1 + \left\{ \frac{x^2}{2} + 2x(y_1 - xy_2) - 2y_2 \right\} dy_2 = 0,$$

whence

$$\frac{dy_2}{dy_1} = \frac{2(y_1 - xy_2) + x}{\frac{x^2}{2} + 2x(y_1 - xy_2) - 2y_2}.$$

Equating the denominator of this expression to 0, we find

$$y_2 = \frac{x^2 + 4xy_1}{4(x^2 + 1)},$$

and substituting this value in the given differential equation, clearing of fractions, and dividing by  $x^2 + 1$ , which will present itself as a common factor,

$$16x^2y + 16y - 8x^3y_1 - 16xy_1 - 16y_1^2 + x^4 = 0,$$

a singular integral. The equation given and the result agree with those of Ex. 1.

## EXERCISES.

$$1. \quad \frac{d^2y}{dx^2} = x + \sin x.$$

$$2. \quad \frac{d^2y}{dx^2} = \frac{-a}{(2ax - x^2)^{\frac{3}{2}}}.$$

$$3. \quad \frac{d^2y}{dx^2} = \frac{1}{\sqrt{(ay)}}.$$

$$4. \quad \frac{d^2y}{dx^2} + \frac{1}{x} \frac{dy}{dx} = 0.$$

$$5. \quad \frac{d^2y}{dx^2} = \frac{2y}{x^2}.$$

$$6. \quad (1 + x^2) \frac{d^2y}{dx^2} + 1 + \left(\frac{dy}{dx}\right)^2 = 0.$$

$$7. \quad y \frac{d^2y}{dx^2} + \left(\frac{dy}{dx}\right)^2 = 1.$$

The two following are reducible to Clairaut's form.

$$8. \quad \frac{dy}{dx} - x \frac{d^2y}{dx^2} = f\left(\frac{d^2y}{dx^2}\right).$$

$$9. \quad \left(\frac{dy}{dx}\right)^2 - y \frac{d^2y}{dx^2} = \frac{dy}{dx} f\left\{\left(\frac{dy}{dx}\right)^{-1} \frac{d^2y}{dx^2}\right\}.$$

10. Describe the different kinds of homogeneity in differential equations, and explain their connexion.

The two following homogeneous equations are intended to be solved by the method developed in Art. 3.

$$11. \quad x^4 \frac{d^2y}{dx^2} = \left(y - x \frac{dy}{dx}\right)^3.$$

$$12. \quad x^4 \frac{d^3y}{dx^3} - x^3 \frac{dy}{dx} = x^2 \left(\frac{dy}{dx}\right)^2 - 4y^2.$$

13. Shew that the linear equation  $\frac{d^2y}{dx^2} + P\frac{dy}{dx} + Qy = 0$ , belongs to one of the homogeneous classes, and is reducible to an equation of the first order by assuming  $y = e^{\int u dx}$ .

14. Solve the linear equation  $\frac{d^2y}{dx^2} + P\frac{dy}{dx} + \frac{dP}{dx}y = 0$ .

15. Mainardi has remarked (Tortolini, Vol. I. p. 76), that Liouville's equation Art. 7, becomes integrable if multiplied by the factor  $\left(\frac{dy}{dx}\right)^{-1}$ . Applying this method, deduce the complete primitive.

16. Liouville's equation may also be solved by suppressing the *second* term and regarding the arbitrary constant in the first integral of the result as an unknown function of  $x$ .

17. Shew that the equation  $\frac{d^2y}{dx^2} + P\frac{dy}{dx} + Q\left(\frac{dy}{dx}\right)^2 = 0$  is integrable in the following cases, viz. 1st, when  $P$  and  $Q$  are both functions of  $x$ , 2ndly, when they are both functions of  $y$ , 3rdly, when  $P$  is a function of  $x$ , and  $Q$  a function of  $y$ .

18. Given  $\left(\frac{dy}{ds}\right)^2 = a \frac{dx}{ds} \frac{d^2x}{ds^2}$ .

19. Given  $s = \sqrt{(x^2 + y^2)}$ . (Transform to polar co-ordinates.)

20. Given  $s = a \frac{dy}{dx}$ . Determine the relation between  $y$  and  $x$ , so that when  $x = 0$ , we may have  $y = 0$ , and  $\frac{dy}{dx} = 0$ .

21. Equations homogeneous with respect to  $x, y$ , and  $s$  can be integrated by the assumption  $x = e^\theta$ ,  $y = e^\theta u$ .

22. Given  $\frac{ds}{dy} + 3y \frac{d^2s}{dy^2} = 0$ , required the complete primitive relation between  $x$  and  $y$ .

23.  $s = \sqrt{(x^2 + 2cx)}$ .

24.  $s = \sqrt{(y^2 + mx^2)}$ .

25. Examine the solution of Ex. 24, when  $m = 1$  and when  $m = 0$ .

$$26. \quad \frac{d^2x}{dt^2} = -\frac{\mu}{x^3} + \frac{k}{x^3} \left( \frac{dx}{dt} \right)^2.$$

27. Shew that  $x \frac{d^2y}{dx^2}$  is an exact differential coefficient.

28. Shew that  $y^2 + (2xy - 1) \frac{dy}{dx} + x \frac{d^2y}{dx^2} + x^2 \frac{d^3y}{dx^3} = 0$  is an exact differential equation, and deduce a first integral.

29. The equation  $\frac{d^2y}{dx^2} + \frac{a^2y}{(y^2 + x^2)^2} = 0$  becomes integrable by means of the factor  $2x^2 \frac{dy}{dx} - 2xy$ . (Moigno, Tom. II. p. 672.) Deduce hence a first integral.

30. Deduce also the complete primitive.

31. Find a singular integral of the equation

$$\left( \frac{d^2y}{dx^2} \right)^2 - \frac{2}{x} \frac{dy}{dx} \frac{d^2y}{dx^2} + 1 = 0.$$

32. Hence deduce a singular solution of the given differential equation.

33. The complete primitive of the differential equation of the second order in Ex. 31 is required.

34. A first integral of the differential equation of the second order  $y - xy_1 + \frac{x^2}{2} y_2 - (y_1 - xy_2)^2 - y_2^2 = 0$  is

$y + \left( \frac{a}{2} - a^2 \right) x^2 - (1 - 2a) xy_1 - a^2 - y_1^2 = 0$ , where  $y_1$  stands for  $\frac{dy}{dx}$ . Hence deduce the singular integral. Shew that it agrees, and ought to agree, with the result obtained in Art. 10.

35. Shew that the complete primitive of the above differential equation is  $y = \frac{a}{2} x^2 + bx + a^2 + b^2$ .

36. The singular integral of the differential equation of the second order, above referred to, has been found to be

$$16(1+x^2)y - 8x^3y_1 - 16xy_1 + x^4 - 16y_1^2 = 0. \quad \text{Ex. 2, Art. 10.}$$

Shew that this singular integral has for its complete primitive

$$(16y + 4x^2 + x^4)^{\frac{1}{2}} = x(1+x^2)^{\frac{1}{2}} - \log \{(1+x^2)^{\frac{1}{2}} - x\} + h,$$

$h$  being an arbitrary constant—and that this is a singular solution of the proposed differential equation of the second order.

37. The same singular integral has for its singular solution  $16y + 4x^2 + x^4 = 0$ . Prove this. Have we a right to expect that this will satisfy the differential equation of the second order?

38. By reasoning similar to that of Chap. VIII. Art. 14, shew that a singular integral of a differential equation of the form  $y_n + f(x, y, y_1 \dots y_{n-1}) = 0$  will render the integrating factor of that equation infinite.

39. Differential equations of the form  $\frac{d^2y}{dx^2} = f\left(\frac{dy}{dx}\right)$  can be integrated by obtaining two first integrals of the respective forms  $x = f(p, c)$ ,  $y = f_1(p, c)$ , and equating the values of  $p$ .

40. Prove the assertion in Art. 9, that a singular solution of a singular integral of a differential equation of the second order is in general no solution at all of the equation given.

## CHAPTER XI.

### GEOMETRICAL APPLICATIONS.

1. IN what manner differential equations afford the appropriate expressions of those properties of curves which involve the ideas of direction, tangency or curvature, has been explained in Chap. I. Art. 11.

Of the suggested problem in which from the expression of a property involving some one or more of the above elements it is required to determine, by the solution of a differential equation, the family of curves to which that property belongs, some illustrations have also been given in the foregoing Chapters.

Here we propose to consider that problem somewhat more generally.

The following expressions furnished by the Differential Calculus are convenient for reference.

For a plane curve referred to rectangular co-ordinates  $x$  and  $y$ , representing also  $\frac{dy}{dx}$  by  $p$ ,  $\frac{d^2y}{dx^2}$  by  $q$ ,

$$\text{Tangent} = \frac{y(1+p^2)^{\frac{1}{2}}}{p}. \quad \text{Subtan.} = \frac{y}{p}.$$

$$\text{Normal} = y(1+p^2)^{\frac{1}{2}}. \quad \text{Subnormal} = yp.$$

$$\text{Intercept on axis } x = x - \frac{y}{p}.$$

$$\text{Intercept on axis } y = y - xp.$$

$$\text{Dist. from origin to foot of normal} = x + yp.$$

$$\text{Perpendicular from } (a, b) \text{ on tangent} = \frac{y - b - (x - a)p}{(1 + p^2)^{\frac{1}{2}}}.$$

$$\text{Perpendicular from } (a, b) \text{ on normal} = \frac{a - x + (b - y)p}{(1 + p^2)^{\frac{1}{2}}}.$$

$$\text{Radius of curvature} = \mp \frac{(1 + p^2)^{\frac{3}{2}}}{q}.$$

Co-ordinates  $(\alpha, \beta)$  of centre of curvature

$$\alpha = x - \frac{p(1 + p^2)}{q}, \quad \beta = y + \frac{1 + p^2}{q}.$$

To these may be added the well-known formulæ for the differentials of arcs, areas, &c.

It is evident from the above forms that problems which relate only to direction or tangency, give rise to differential equations of the first order—problems which involve the conception of curvature to equations of the second order.

When the conditions of a geometrical problem have been expressed by a differential equation, and that equation has been solved, it will still be necessary to determine the species of the solution—general, particular, or singular, as also its geometrical significance.

2. The class of problems which first presents itself, is that in which it is required to determine a family of curves by the condition that some one of the elements whose expressions are given above shall be constant.

Ex. 1. Required to determine the curves whose subnormal is constant.

Here  $y \frac{dy}{dx} = a$ , and integrating,

$$\frac{y^2}{2} = ax + c,$$

$$y = (2ax + 2c)^{\frac{1}{2}}.$$

The property is seen to belong to the parabola whose parameter is double of the constant distance in question, and whose axis coincides with the axis of  $x$ , while the position of the vertex on that axis is arbitrary.

Ex. 2. Required a curve in which the perpendicular from the origin upon the tangent is constant and equal to  $a$ .

Here we have

$$y - xp = a(1 + p^2)^{\frac{1}{2}},$$

an equation of Clairaut's form, of which the complete primitive is

$$y = cx + (1 + c^2)^{\frac{1}{2}} a,$$

and the singular solution

$$x^2 + y^2 = a^2.$$

The former denotes a family of straight lines whose distance from the origin is equal to  $a$ , the latter a circle whose centre is at the origin, and whose radius is equal to  $a$ . And here, as was noted generally by Lagrange, the singular solution seems to be, in relation to geometry, the more important of the two.

3. A more general class of problems is that in which it is required to determine the curves in which some one of the foregoing elements, Art. 1, is equal to a given function of the abscissa  $x$ .

Ex. 1. Required the class of curves in which the subtangent is equal to  $f(x)$ .

Here we have

$$y = f(x) \frac{dy}{dx};$$

whence 
$$\frac{dy}{y} = \frac{dx}{f(x)},$$

$$y = C e^{\int \frac{dx}{f(x)}}.$$

Thus if the proposed function were  $x^2$ , we should have

$$y = C e^{-\frac{1}{x}},$$

as the equation required.

Ex. 2. Required the family of curves in which the radius of curvature is equal to  $f(x)$ .

Here we have

$$\frac{\frac{d^2y}{dx^2}}{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}^{\frac{3}{2}}} = \mp \frac{1}{f(x)},$$

whence, multiplying by  $dx$  and integrating,

$$\frac{\frac{dy}{dx}}{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}^{\frac{1}{2}}} = \mp \int \frac{dx}{f(x)}$$

$$= \mp (X + C),$$

$X$  representing the integral of  $\frac{dx}{f(x)}$ . Hence we find by algebraic solution

$$\frac{dy}{dx} = \frac{X + C}{\{1 - (X + C)^2\}^{\frac{1}{2}}},$$

$$y = \int \frac{(X + C) dx}{\{1 - (X + C)^2\}^{\frac{1}{2}}} + C_1,$$

in which it only remains to substitute for  $X$  its value, and effect the remaining integration.

If  $f(x)$  is constant and equal to  $a$ , we find

$$X + C = \frac{x}{a} + C = \frac{x + aC}{a},$$

$$y = \int \frac{(x + aC) dx}{\sqrt{a^2 - (x + aC)^2}} + C_1,$$

$$= -\{a^2 - (x + aC)^2\}^{\frac{1}{2}} + C_1,$$

whence  $(y - C_1)^2 + (x + aC)^2 = a^2$ ,

and this represents a circle whose centre is arbitrary in position, and whose radius is  $a$ .

A yet more general class of problems is that in which it is required that one of the elements expressed in Art. 1 should be expressed by a given function of  $x$  and  $y$ .

An example of this class is given in Chap. VII. Art. 10.

4. We proceed in the next place to consider certain problems in which more than one of the elements expressed in Art. 1, are involved,

Ex. 1. To determine the curves in which the radius of curvature is equal to the normal.

If the radius of curvature have the same direction as the normal we shall have

$$\frac{-\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}^{\frac{3}{2}}}{\frac{d^2y}{dx^2}} = y \left\{1 + \left(\frac{dy}{dx}\right)^2\right\}^{\frac{1}{2}} \dots\dots\dots(1),$$

whence

$$y \frac{d^2y}{dx^2} + \left(\frac{dy}{dx}\right)^2 + 1 = 0 \dots\dots\dots(2).$$

The first side multiplied by  $dx$  is an exact differential and gives

$$y \frac{dy}{dx} + x = c,$$

whence again integrating

$$y^2 + x^2 = 2cx + c' \dots\dots\dots(3),$$

the equation of a circle whose centre is on the axis of  $x$ .

If the direction of the radius of curvature be opposite to that of the normal, it will be necessary to change the sign of the first member of (1). Instead of (2) we shall have

$$y \frac{d^2y}{dx^2} - \left(\frac{dy}{dx}\right)^2 - 1 = 0 \dots\dots\dots(4),$$

and this equation not containing  $x$ , we may depress it to the first order by assuming  $\frac{dy}{dx} = p$ . The transformed equation is

$$yp \frac{dp}{dy} - p^2 - 1 = 0,$$

whence

$$\frac{pdp}{p^2 + 1} = \frac{dy}{y}$$

$$y = c (1 + p^2)^{\frac{1}{2}}.$$

Substituting for  $p$  its value  $\frac{dy}{dx}$ , we find on algebraic solution

$$dx = \frac{cdy}{\sqrt{(y^2 - c^2)}},$$

whence  $x = c' + c \log \{y + (y^2 - c^2)^{\frac{1}{2}}\} \dots\dots\dots(5).$

This equation, reduced to the exponential form

$$y = \frac{a}{2} \left( \epsilon^{\frac{x-b}{a}} + \epsilon^{-\frac{x-b}{a}} \right), \dots\dots\dots(6),$$

is seen to represent a catenary.

The solution therefore indicates a circle when the directions of the radius of curvature and of the normal are the same, but a catenary when they are opposed. The latter curve has, however, many properties analogous to those of the circle. (Lacroix, Tom. II. p. 459.)

Ex. 2. To find a curve in which the area, as expressed by the formula  $\int y dx$ , is in a constant ratio to the corresponding arc.

We have  $y = C(1 + p^2)^{\frac{1}{2}},$

which, agreeing in form with the last differential equation of the preceding problem, shews that (5) represents the curve required, and connects together the properties noticed in the last two examples.

Ex. 3. Required the class of curves in which the length of the normal is a given function of the distance of its foot from the origin.

The differential equation is

$$y(1 + p^2)^{\frac{1}{2}} = f(x + yp) \dots\dots\dots(1),$$

and it belongs to the remarkable class discussed in Chap. VII. Art. 9, where the complete primitive is given, viz.

$$y^2 + (x - a)^2 = \{f(a)\}^2 \dots\dots\dots(2).$$

This represents a circle whose centre is situated on the axis of  $x$  at a distance  $a$  from the origin, and whose radius is equal to

$f'(a)$ . It is evident that this circle satisfies the geometrical conditions of the problem.

But there is also a singular solution, found by eliminating the constant  $a$  between (2) and the equation derived from (2) by differentiation with respect to  $a$ , viz.

$$x - a + f'(a)f''(a) = 0 \dots\dots\dots(3).$$

For instance, if  $f(a) = n^{\frac{1}{2}}a^{\frac{1}{2}}$  we have to eliminate  $a$  between the equations

$$y^2 + (x - a)^2 = na,$$

$$2(x - a) + n = 0,$$

from which we find

$$y^2 = nx + \frac{n^2}{4},$$

the equation of a parabola. While in this example the complete primitive represents circles only, the singular solution represents an infinite variety of distinct curves, each originating in a distinct form of the function  $f'(a)$ . Other illustrations of this remark will be met with.

The above problem was first discussed by Leibnitz, who did not, however, regard its solution as dependent upon that of a differential equation, but, establishing by independent considerations the equation (2), which constitutes in the above mode of treatment the complete primitive of a differential equation, arrived at a result equivalent to its singular solution by that kind of reasoning which is employed in the geometrical theory of envelopes. Indeed it was in the discussion of this problem that the foundations of that theory were laid (Lagrange, *Calcul des Fonctions*, p. 268).

5. A certain historic interest belongs also to the two following problems, famous in the earlier days of the Calculus, viz. the problem of 'Trajectories' and the problem of 'Curves of Pursuit.' These we shall consider next. They will serve to illustrate in some degree the modes of consideration by which the differential equations of a problem are formed when a mere table of analytical expressions suffices no longer.

*Trajectories.*

Supposing a system of curves to be described, the different members differing only through the different values given to an arbitrary constant in their common equation—a curve which intersects them all at a constant angle is called a trajectory, and when the angle is right, an orthogonal trajectory.

To determine the orthogonal trajectory of a system of curves represented by the equation

$$\phi(x, y, c) = 0 \dots\dots\dots(1).$$

Representing for brevity  $\phi(x, y, c)$  by  $\phi$ , we have on differentiating

$$\frac{d\phi}{dx} dx + \frac{d\phi}{dy} dy = 0.$$

Hence, for the intersected curves,

$$\frac{dy}{dx} = - \frac{d\phi}{dx} \div \frac{d\phi}{dy}.$$

Now representing this value by  $m$ , and the corresponding value of  $\frac{dy}{dx}$  for the trajectory by  $m'$ , we have, by the condition

of perpendicularity,  $m' = -\frac{1}{m}$ . Hence for the trajectory

$$\frac{dy}{dx} = \frac{d\phi}{dy} \div \frac{d\phi}{dx},$$

or

$$\frac{d\phi}{dy} dx - \frac{d\phi}{dx} dy = 0 \dots\dots\dots(2),$$

which must be true for all values of  $c$ . Hence the *differential equation of the orthogonal trajectory will be found by eliminating  $c$  between (1) and (2).*

Were the equation of the system of intersected curves presented in the form

$$\phi(x, y, a, b) = 0,$$

$a$  and  $b$  being connected by a condition

$$\psi(a, b) = 0,$$

we should have to eliminate  $a$  and  $b$  between the above two equations, and the equation

$$\frac{d\phi(x, y, a, b)}{dy} dx - \frac{d\phi(x, y, a, b)}{dx} dy = 0.$$

We shall exemplify both forms of the problem.

Ex. 1. Required the orthogonal trajectory of the system of curves represented by the equation  $y = cx^n$ .

Here  $\phi = y - cx^n$ , whence by (2)

$$dx + ncx^{n-1} dy = 0.$$

Eliminating  $c$ ,

$$x dx + ny dy = 0;$$

therefore

$$x^2 + ny^2 = c',$$

the equation required. We see that the trajectory will be an ellipse for all positive values of  $n$  except  $n = 1$ ,—an ellipse, therefore, when the intersected curves are a system of common parabolas. The trajectory is a circle if  $n = 1$ , the intersected system then being one of straight lines passing through the origin. The trajectory is an hyperbola if  $n$  is negative.

Ex. 2. Required the orthogonal trajectory of a system of confocal ellipses.

The general equation of such a system is

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1,$$

$a$  and  $b$  being connected by the condition

$$a^2 - b^2 = h^2,$$

where  $h$  is the semi-distance of the foci, and does not vary from curve to curve. Hence we have to eliminate  $a$  and  $b$  from the above equations, and the equation

$$\frac{y}{b^2} dx - \frac{x}{a^2} dy = 0;$$

the result is

$$xy \left( \frac{dy}{dx} \right)^2 + (x^2 - y^2 - h^2) \frac{dy}{dx} - xy = 0,$$

the solution of which may be deduced from that of Ex. 3, Chap. VII. Art. 10, by assuming therein  $A = 1$ ,  $B = h^2$ . We find

$$y^2 - c^2 x^2 = - \frac{h^2 c^2}{c^2 + 1},$$

and this may be reduced to the form

$$\frac{x^2}{a_1^2} - \frac{y^2}{b_1^2} = 1,$$

$a_1$  and  $b_1$  being connected by the condition

$$a_1^2 + b_1^2 = h^2.$$

Thus the trajectory is an hyperbola confocal with the given system of ellipses.

6. When the trajectory is oblique, then  $\theta$  being the angle which it makes with each curve of the system, and  $m$  and  $m'$  having the same significations as before,

$$m' = \frac{m + \tan \theta}{1 - m \tan \theta},$$

or, substituting for  $m$  its former value  $-\frac{d\phi}{dx} \div \frac{d\phi}{dy}$ , and for  $m'$  its value  $\frac{dy}{dx}$  as referred to the trajectory, we have on reduction

$$\frac{dy}{dx} = \frac{\frac{d\phi}{dy} \tan \theta - \frac{d\phi}{dx}}{\frac{d\phi}{dy} + \frac{d\phi}{dx} \tan \theta} \dots\dots\dots (3),$$

an equation from which it only remains to eliminate  $c$  by means of the given equation in order to obtain the differential equation of the trajectory.

Ex. Required the general equation of the trajectories of the system of straight lines  $y = ax$ .

Here  $\phi = y - ax$ , whence by (3)

$$\begin{aligned}\frac{dy}{dx} &= \frac{\tan \theta + a}{1 - a \tan \theta} \\ &= \frac{x \tan \theta + y}{x - y \tan \theta},\end{aligned}$$

or  $(y + x \tan \theta) dx + (y \tan \theta - x) dy = 0$ ,

a homogeneous equation, an integrating factor of which being  $\frac{1}{x^2 + y^2}$ , we have

$$\frac{y dx - x dy}{x^2 + y^2} + \tan \theta \frac{x dx + y dy}{x^2 + y^2} = 0,$$

whence integrating

$$\tan^{-1} \frac{x}{y} + \tan \theta \log (x^2 + y^2)^{\frac{1}{2}} = c.$$

If we change the co-ordinates by assuming  $x = r \cos \phi$ ,  $y = r \sin \phi$ , we get

$$r = C_1 e^{\frac{\phi}{\tan \theta}},$$

the equation of a logarithmic spiral.

The following example, which is taken from a Memoir by Mainardi (Tortolini's *Annali di Scienze Matematiche e Fisiche*, Tom. I. 251), is chiefly interesting from the mode in which the integration is effected.

Required the oblique trajectory of a system of confocal ellipses.

Representing the tangent of the angle of intersection by  $n$ , we have to eliminate  $a$  and  $b$  between the equations

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, \quad a^2 - b^2 = h^2,$$

$$p = \frac{n \frac{y}{b^2} - \frac{x}{a^2}}{\frac{y}{b^2} + n \frac{x}{a^2}}.$$

The result may be expressed in the form

$$\{nx + y + (ny - x)p\} \{x - ny + (nx + y)p\} = h^2 (n - p)(1 + np).$$

To integrate this equation let us assume

$$\begin{aligned} x - ny + (nx + y)p &= M(1 + np), \\ M \{nx + y + (ny - x)p\} &= h^2 (n - p). \end{aligned}$$

As these on multiplication reproduce the given equation the assumption is legitimate.

Eliminating  $p$  from the last two equations, and dividing by  $1 + n^2$ , we have

$$(x^2 + y^2 + h^2) M = x (M^2 + h^2) \dots\dots\dots (a).$$

Differentiating this equation and eliminating  $y$  and  $p$  from the result by the aid of any two of the last three equations (it is evident that two only are independent), we obtain a differential equation between  $M$  and  $x$ , which is capable of expression in the form

$$\frac{nd(xM)}{\{h^2(xM) - (xM)^2\}^{\frac{1}{2}}} + \frac{\frac{dM}{x}}{\frac{M}{x} \left(1 - \frac{M}{x}\right)^{\frac{1}{2}}} = 0 \dots\dots\dots (b).$$

[For (a) may be written thus :

$$My^2 = (x - M)(h^2 - xM) \dots\dots\dots (c) ;$$

differentiating we have

$$\begin{aligned} 2y \frac{dy}{dx} M + y^2 \frac{dM}{dx} \\ = \left(1 - \frac{dM}{dx}\right)(h^2 - xM) - (x - M) \left(M + x \frac{dM}{dx}\right) ; \end{aligned}$$

therefore 
$$2y \frac{dy}{dx} M + \frac{(x - M)(h^2 - xM)}{M} \frac{dM}{dx}$$

$$= \left(1 - \frac{dM}{dx}\right)(h^2 - xM) - (x - M) \left(M + x \frac{dM}{dx}\right) ;$$

therefore 
$$2y \frac{dy}{dx} M + \frac{x(h^2 - xM)}{M} \frac{dM}{dx}$$

$$= h^2 - xM - (x - M) \left( M + x \frac{dM}{dx} \right);$$

therefore 
$$2y \frac{dy}{dx} M + \frac{x(h^2 - M^2)}{M} \frac{dM}{dx} = h^2 - 2xM + M^2.$$

But 
$$\frac{dy}{dx} = \frac{M + ny - x}{n(x - M) + y},$$

therefore 
$$2My(M - x) + 2nMy^2$$

$$= y \left\{ h^2 - 2xM + M^2 - \frac{x}{M} (h^2 - M^2) \frac{dM}{dx} \right\}$$

$$+ n(x - M) \left\{ h^2 - 2xM + M^2 - \frac{x}{M} (h^2 - M^2) \frac{dM}{dx} \right\};$$

therefore

$$y(M^2 - h^2) + 2n(x - M)(h^2 - xM) + \frac{yx}{M}(h^2 - M^2) \frac{dM}{dx}$$

$$= n(x - M) \left\{ h^2 - 2xM + M^2 - \frac{x}{M} (h^2 - M^2) \frac{dM}{dx} \right\};$$

therefore 
$$(M^2 - h^2) \left( y - \frac{yx}{M} \frac{dM}{dx} \right) - n(x - M)(M^2 - h^2)$$

$$= n(x - M) \frac{x}{M} (M^2 - h^2) \frac{dM}{dx};$$

therefore 
$$y - \frac{yx}{M} \frac{dM}{dx} - n(x - M) = n(x - M) \frac{x}{M} \frac{dM}{dx};$$

therefore 
$$n(x - M) \left( M + x \frac{dM}{dx} \right) + y \left( x \frac{dM}{dx} - M \right) = 0;$$

therefore 
$$n(x - M) \frac{d(xM)}{dx} + yx^2 \frac{d}{dx} \frac{M}{x} = 0.$$

Hence by the aid of (c) we obtain (b).]

Hence, by integration

$$-2n \tan^{-1} \sqrt{\left(\frac{h^2}{xM} - 1\right)} + \log \frac{1 - \sqrt{\left(1 - \frac{M}{x}\right)}}{1 + \sqrt{\left(1 - \frac{M}{x}\right)}} = C,$$

in which it is only necessary to substitute for  $M$  its value in terms of  $x$  and  $y$  deduced from (a).

### *Curves of Pursuit.*

7. The term curve of pursuit is given to the path which a point describes when moving with uniform velocity towards another point which moves with uniform velocity in a given curve.

Let  $x, y$  be the co-ordinates of the pursuing point,  $x', y'$  the simultaneous co-ordinates of the point pursued. Also let the equation of the given path of the latter be

$$f(x', y') = 0 \dots\dots\dots (4).$$

Now the point pursued being always in the tangent to the path of the point which pursues, its co-ordinates must satisfy the equation of that tangent. Hence,

$$y' - y = \frac{dy}{dx} (x' - x) \dots\dots\dots (5).$$

Lastly, the velocities of the two points being uniform, the corresponding elementary arcs will be in the constant ratio of the velocities with which they are described. Hence, if the velocity of the pursuing point be to that of the point pursued as  $n : 1$ , we have

$$n \sqrt{(dx')^2 + (dy')^2} = \sqrt{(dx)^2 + (dy)^2},$$

or, taking  $x$  as independent variable,

$$n \sqrt{\left\{\left(\frac{dx'}{dx}\right)^2 + \left(\frac{dy'}{dx}\right)^2\right\}} = \sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}} \dots\dots\dots (6),$$

the sign to be given to each radical being positive or negative, according as the motion tends to increase or to diminish the corresponding arc.

From (4) and (5), when the form of the function  $f(x', y')$  is determined,  $x'$  and  $y'$  may be found in terms of  $x$ ,  $y$ , and  $\frac{dy}{dx}$ , and these values enable us to reduce (6) to an equation between  $x$ ,  $y$ ,  $\frac{dy}{dx}$ ,  $\frac{d^2y}{dx^2}$ . It only remains to solve this differential equation of the second order. If the signs of the radicals are both changed, the motion in each curve is simply reversed, and the curve of pursuit becomes a curve of flight. But the differential equation remaining unchanged, the forms of the curves are unchanged, and only their relation inverted.

Ex. A particle which sets off from a point in the axis of  $x$ , situated at a distance  $a$  from the origin, and moves uniformly in a vertical direction parallel to the axis of  $y$ , is pursued by a particle which sets off at the same moment from the origin and travels with a velocity which is to that of the former as  $n : 1$ . Required the path of the latter.

The equation of the path of the first particle being  $x' = a$ , (5) becomes

$$y' - y = \frac{dy}{dx} (a - x),$$

whence

$$y' = y + (a - x) \frac{dy}{dx}.$$

Thus we have

$$\frac{dx'}{dx} = 0, \quad \frac{dy'}{dx} = (a - x) \frac{d^2y}{dx^2},$$

and the differential equation, both radicals being positive, is

$$n(a - x) \frac{d^2y}{dx^2} = \sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}} \dots\dots\dots (a).$$

Hence

$$\frac{\frac{d^2y}{dx^2}}{\sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}}} = \frac{1}{n(a-x)}.$$

Multiplying by  $dx$  and integrating

$$\frac{dy}{dx} + \sqrt{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}} = c(a-x)^{-\frac{1}{n}};$$

therefore 
$$\frac{dy}{dx} = \frac{1}{2} \left\{ c(a-x)^{-\frac{1}{n}} - \frac{1}{c}(a-x)^{\frac{1}{n}} \right\}.$$

Hence, if  $n$  be not equal to 1,

$$y = \frac{1}{2} \left\{ \frac{c(a-x)^{1-\frac{1}{n}}}{\frac{1}{n} - 1} + \frac{1}{c} \frac{(a-x)^{1+\frac{1}{n}}}{1 + \frac{1}{n}} \right\} + c' \dots\dots\dots (b).$$

But if  $n$  be equal to 1, we have

$$\frac{dy}{dx} = \frac{1}{2} \left\{ \frac{x-a}{c} - \frac{c}{x-a} \right\},$$

whence

$$y = \frac{(x-a)^2}{4c} - \frac{c}{2} \log(x-a) + c'.$$

8. The class of problems which we shall next consider is introduced chiefly on account of the instructive light which it throws upon the singular solutions of differential equations of the second order.

### *Inverse Problems in Geometry and Optics.*

The problems we are about to discuss are the following: 1st, To determine the involute of a plane curve. 2ndly, To determine the form of the reflecting curve which will produce a given *caustic*, the incident rays being supposed parallel.

In both these problems we shall have occasion in a particular part of the process to solve a differential equation of the first order of the form

$$y - x\phi(p) = ff'^{-1}\phi(p) - \phi(p)f'^{-1}\phi(p) \dots\dots(7),$$

in which  $\phi$  and  $f$  are functional symbols of given interpretation, and  $f'^{-1}$  is a functional symbol whose interpretation is inverse to that of the symbol  $f'$ . Thus, if  $f(x) = \sin x$ , then

$$f'(x) = \cos x, \quad f'^{-1}(x) = \cos^{-1} x.$$

It will somewhat less interrupt the theoretical observations for the sake of which the above problems are chiefly valuable, if we solve the equation (7) under its general form first.

Referring to Chap. VII. Art. 7, we see that (7) will become linear if we transform it so as to make either of the primitive variables the dependent variable, and either  $p$  or any function of  $p$  the independent variable.

Let us then assume

$$\phi(p) = v,$$

and transform the differential equation so as to make  $x$  and  $v$  the new variables.

Substituting  $v$  for  $\phi(p)$  in (7), we have

$$y - xv = ff'^{-1}(v) - vf'^{-1}(v) \dots\dots\dots(8).$$

Differentiating, and regarding  $v$  as independent variable,

$$\begin{aligned} \frac{dy}{dv} - x - v \frac{dx}{dv} &= v \frac{d}{dv} f'^{-1}(v) - f'^{-1}(v) - v \frac{d}{dv} f'^{-1}(v) \\ &= -f'^{-1}(v). \end{aligned}$$

But

$$\frac{dy}{dv} = p \frac{dx}{dv} = \phi^{-1}(v) \frac{dx}{dv}.$$

Hence,

$$\{\phi^{-1}(v) - v\} \frac{dx}{dv} - x = -f'^{-1}(v),$$

or,

$$\frac{dx}{dv} + \frac{x}{v - \phi^{-1}(v)} = \frac{f'^{-1}(v)}{v - \phi^{-1}(v)}.$$

Hence, if for brevity we write

$$\int \frac{dv}{v - \phi^{-1}(v)} = \psi(v) \dots\dots\dots (9),$$

we have

$$\begin{aligned} x &= \epsilon^{-\psi(v)} \left\{ C + \int \epsilon^{\psi(v)} \psi'(v) f'^{-1}(v) dv \right\} \\ &= \epsilon^{-\psi(v)} \left\{ C + \epsilon^{\psi(v)} f'^{-1}(v) - \int \epsilon^{\psi(v)} df'^{-1}(v) \right\}, \end{aligned}$$

whence

$$x - f'^{-1}(v) = \epsilon^{-\psi(v)} \left\{ C - \int \epsilon^{\psi(v)} df'^{-1}(v) \right\} \dots\dots\dots (10),$$

between which and (8),  $v$  must be eliminated.

If in those equations we make  $f'^{-1}(v) = t$ , they assume the somewhat more convenient form,

$$\begin{aligned} y - xf''(t) &= f'(t) - tf'(t), \\ x - t &= \epsilon^{-\psi f''(t)} \left\{ C - \int \epsilon^{\psi f''(t)} dt \right\}, \end{aligned}$$

and these may yet further be reduced to the form

$$x - t = \frac{y - f(t)}{f'(t)} = \frac{C - \int \epsilon^{\psi f''(t)} dt}{\epsilon^{\psi f''(t)}} \dots\dots\dots (11).$$

From these equations it only remains to eliminate  $t$ , the forms of  $f$  and  $\phi$  being specified, and that of  $\psi$  given by (9); and this is apparently the simplest form of the solution.

9. We shall now proceed to the special problems under consideration.

To determine the involute of a plane curve.

It is evident from the equations which present themselves in the investigation of the radius of curvature, that if  $x, y$  be the co-ordinates of any point in a plane curve, and  $x', y'$  those of the corresponding point in the evolute, then

$$x' = x - \frac{p(1+p^2)}{q}, \quad y' = y + \frac{1+p^2}{q},$$

where  $p = \frac{dy}{dx}$ ,  $q = \frac{d^2y}{dx^2}$  (Todhunter's *Differential Calculus*, Art. 320). Hence, if the equation of the evolute be

$$y' = f(x') \dots\dots\dots(12),$$

we shall have on substituting therein for  $y'$  and  $x'$  the values above given,

$$y + \frac{1+p^2}{q} = f\left\{x - \frac{p(1+p^2)}{q}\right\} \dots\dots\dots(13),$$

a differential equation of the second order connecting  $x$  and  $y$ , and therefore true for each point of the curve whose evolute is given. Of that evolute the curve in question is an *involute*. Hence, if  $y' = f(x')$  be the equation of a given curve, the equation of its involute will satisfy the differential equation (13).

Now suppose that nothing was known of the genesis of the above equation, and that it was required to deduce its complete primitive, and its singular solution, should such exist.

Upon examination the equation (13) will prove to be of a kind analogous to that of Chap. VII. Art. 9. If we assume

$$x - \frac{p(1+p^2)}{q} = a \dots\dots\dots(14),$$

$$y + \frac{1+p^2}{q} = b \dots\dots\dots(15),$$

$a$  and  $b$  being arbitrary constants, we shall find that each of these leads by differentiation to the same differential equation of the third order, viz.

$$3pq^2 - (1 + p^2)r = 0 \dots\dots\dots(16),$$

where  $r$  stands for  $\frac{d^3y}{dx^3}$ . It follows hence, that a first integral of (13) will be found by eliminating  $q$  between (14) and (15), and connecting the arbitrary constants  $b$  and  $a$  by the relation  $b = f(a)$ . Eliminating  $q$ , we find

$$x - a + (y - b)p = 0 \dots\dots\dots(17),$$

wherein making  $b = f(a)$ , we have

$$x - a + \{y - f(a)\}p = 0 \dots\dots\dots(18),$$

for the first integral in question. Again, integrating, we have

$$(x - a)^2 + \{y - f(a)\}^2 = r^2 \dots\dots\dots(19),$$

in which  $a$  and  $r$  are arbitrary constants. This is the complete primitive of (13). It is manifest from its form that it represents, not the involute of the given curve, but the circles of curvature of that involute. Indeed, that the complete primitive cannot represent the involute might have been affirmed *a priori*. The equation of the involute of a given curve cannot involve in its expression more than *one* arbitrary constant; for the only element left arbitrary in the mechanical genesis of the involute is the length of a string.

It remains to examine the singular solution of (13). This is most easily deduced by eliminating  $a$  between the first integral (18) and its derived equation with respect to  $a$ , viz. between the equations

$$x - a + \{y - f(a)\}p = 0 \dots\dots\dots(20),$$

$$-1 - f'(a)p = 0 \dots\dots\dots(21).$$

From the second of these we have

$$f'(a) = -\frac{1}{p},$$

$$a = f'^{-1}\left(-\frac{1}{p}\right).$$

Hence eliminating  $a$  from (20)

$$x - f'^{-1} \left( \frac{-1}{p} \right) + \left\{ y - ff'^{-1} \left( \frac{-1}{p} \right) \right\} p = 0,$$

or 
$$x + yp = f'^{-1} \left( \frac{-1}{p} \right) + pff'^{-1} \left( \frac{-1}{p} \right) \dots\dots\dots(22),$$

which is the singular solution of (13), and the differential equation of the first order of the involute sought.

This equation is a particular case of (7). If we express it in the form

$$y - \left( \frac{-1}{p} \right) x = ff'^{-1} \left( \frac{-1}{p} \right) - \left( \frac{-1}{p} \right) f'^{-1} \left( \frac{-1}{p} \right),$$

we see that it is what (7) would become on making

$$\phi(p) = \frac{-1}{p}.$$

Hence comparing with the general solution (11) we have

$$\phi(v) = \frac{-1}{v}, \quad \phi^{-1}(v) = \frac{-1}{v},$$

$$\psi(v) = \int \frac{dv}{v + \frac{1}{v}} = \log(v^2 + 1)^{\frac{1}{2}}.$$

Thus the system (11) becomes

$$x - t = \frac{y - f(t)}{f'(t)} = \frac{C - \int \{1 + f'(t)^2\}^{\frac{1}{2}} dt}{\{1 + f'(t)^2\}^{\frac{1}{2}}} \dots\dots(23).$$

The final solution is therefore expressed in the following theorem.

*Given the equation of a curve in the form  $y' = f(x')$ , that of its involute is found by eliminating  $t$  from the system (23).*

10. Parallel rays incident, in a given direction, on a reflecting plane curve produce after reflection a caustic whose equation is given. The equation of the reflecting curve is required.

Let  $IP$  be a ray incident parallel to the axis of  $x$  on a point  $P$  in the reflecting curve  $SPM$ , Fig. 1,  $PP'Q$  the reflected ray cutting the axis of  $x$  in  $Q$  and touching the caustic  $S'P'M'$  in  $P'$ . Let  $x, y$  be the co-ordinates of  $P$ ,  $x', y'$  those of  $P'$ . Let the equation of the caustic be  $y' = f(x')$ .

It is an easy consequence of the law of reflection that the angle  $PQX$  which the reflected ray makes with the axis of  $x$  is double of the angle  $PTX$  made by the tangent at  $P$  with the axis of  $x$ . This at once gives us the equation

$$\frac{y - y'}{x - x'} = \frac{2p}{1 - p^2},$$

where  $p = \frac{dy}{dx}$ . Hence

$$y - y' - \frac{2p}{1 - p^2} (x - x') = 0 \dots\dots\dots (24).$$

As, however,  $(x', y')$  is a point at which consecutive reflected rays intersect, we are permitted to differentiate the above equation regarding  $x'$  and  $y'$  as constant while  $x$  and  $y$  vary. We thus obtain, representing  $\frac{d^2y}{dx^2}$  by  $q$ ,

$$p - \frac{2p}{1 - p^2} - (x - x') \frac{2q(1 - p^2) + 4p^2q}{(1 - p^2)^2} = 0,$$

or 
$$-\frac{p - p^3}{1 - p^2} - (x - x') \frac{2q(1 + p^2)}{(1 - p^2)^2} = 0,$$

whence 
$$x - x' = -\frac{p(1 - p^2)}{2q},$$

and 
$$x' = x + \frac{p(1 - p^2)}{2q} \dots\dots\dots (25).$$

Substituting this value in (24), we have

$$y - y' = \frac{2p}{1 - p^2} \times -\frac{p(1 - p^2)}{2q} = -\frac{p^2}{q},$$

whence 
$$y' = y + \frac{p^2}{q} \dots\dots\dots (26).$$

Were the equation of the reflecting curve given and that of the caustic required, it would only be necessary to substitute in (25) and (26) the values of  $p$  and  $q$  in terms of  $x$  and  $y$  derived from the former, and then by eliminating  $x$  and  $y$  from the three, to deduce the relation between  $x'$  and  $y'$ .

Conversely, to determine the reflecting curve we must eliminate  $x'$  and  $y'$  from (25), (26) and the equation of the caustic, viz.  $y' = f(x')$ . The result which is obtained by mere substitution is

$$y + \frac{p^2}{q} = f \left\{ x + \frac{p(1-p^2)}{2q} \right\} \dots\dots\dots (27),$$

a differential equation of the second order, the solution of which will determine in the fullest manner the possible relations between  $x$  and  $y$  which are consistent with the conditions of the problem.

Were this equation given and nothing known respecting its origin, we might at once infer that it is of a class analogous to those of Chap. VII. Art. 9. For writing

$$y + \frac{p^2}{q} = b, \quad x + \frac{p(1-p^2)}{2q} = a \dots\dots\dots (28),$$

we find that each of these leads by differentiation to the same differential equation of the third order. For the first gives

$$3p - \frac{p^2 r}{q^2} = 0,$$

while the second gives

$$\frac{3}{2} - \frac{3}{2} p^2 - \frac{(1-p^2) pr}{2q^2} = 0,$$

and these lead to the same value of the differential coefficient of the third order,  $r$ , viz.

$$r = \frac{3q^2}{p},$$

this constituting the essential criterion of agreement between differential equations of the third order.

Accordingly, eliminating  $q$  from (28) and afterwards making  $b = f(a)$  by virtue of (27), we find

$$\frac{p}{f'(a) - y} = \frac{1 - p^2}{2(a - x)},$$

or 
$$y - f(a) = \frac{2p}{1 - p^2} (x - a) \dots \dots \dots (29),$$

which is a complete first integral of (27). We see that it agrees, and necessarily so, with (24),  $a$  only taking the place of  $x'$  and  $f(a)$  that of  $y'$ .

The complete integral of (29) will be found to be

$$\{y - f(a)\}^2 = 4m(x - a) + 4m^2 \dots \dots \dots (30),$$

$m$  being an arbitrary constant. And this is the complete primitive of (27). If we substitute  $x'$  for  $a$ , which we may without loss of generality do, then  $f(a) = f(x') = y'$ , so that the above equation gives

$$(y - y')^2 = 4m(x - x' + m) \dots \dots \dots (31);$$

and this is evidently the equation of a parabola whose axis is parallel to the axis of  $x$ , whose focus is upon the caustic curve, but which is in no other way limited. The complete primitive of (27) represents then a system of such parabolas.

It is plain that any such system does constitute a true solution of the problem, rays falling upon the interior arc of a parabola, and parallel to its axis, being accurately reflected to the focus.

It remains to deduce the singular solution of (27). Differentiating its first integral (29) with respect to  $a$ , we have

$$-f'(a) = -\frac{2p}{1 - p^2},$$

whence 
$$a = f'^{-1} \left( \frac{2p}{1 - p^2} \right),$$

and substituting this in (29)

$$y - ff'^{-1} \left( \frac{2p}{1 - p^2} \right) = \frac{2p}{1 - p^2} \left\{ x - f'^{-1} \left( \frac{2p}{1 - p^2} \right) \right\},$$

$$\text{or } y - \frac{2p}{1-p^2}x = ff'^{-1}\left(\frac{2p}{1-p^2}\right) - \frac{2p}{1-p^2}f'^{-1}\left(\frac{2p}{1-p^2}\right) \dots (32).$$

This is the differential equation of the involute. Its complete integral may be deduced from the general solution in Art. 8, by making  $\phi(p) = \frac{2p}{1-p^2}$ , whence we have

$$\phi^{-1}(p) = \frac{-1 - (1 + p^2)^{\frac{1}{2}}}{p},$$

$$\begin{aligned} \psi(v) &= \int \frac{dv}{v - \phi^{-1}(v)} = \int \frac{v dv}{v^2 + 1 + (1 + v^2)^{\frac{1}{2}}} \\ &= \log \{ \sqrt{1 + v^2} + 1 \}. \end{aligned}$$

Hence the system (11) becomes

$$x - t = \frac{y - f(t)}{f'(t)} = \frac{C - \int [1 + \sqrt{1 + f'(t)^2}] dt}{1 + \sqrt{1 + f'(t)^2}} \dots (33),$$

from which, after the integration has been effected,  $t$  must be eliminated.

If, as before, we replace  $t$  by  $x'$ , and  $f(t)$  by  $y'$  and therefore  $f'(t)$  by  $\frac{dy'}{dx'}$ , then, since we have

$$\sqrt{1 + f'(t)^2} dt = ds',$$

where  $s'$  represents the arc of the caustic, the above system assumes the following form,

$$x - x' = \frac{y - y'}{\frac{dy'}{dx'}} = \frac{C - x' - s'}{1 + \frac{ds'}{dx'}} \dots (34),$$

from which, when  $s'$  is determined,  $x'$  and  $y'$  must be eliminated by means of the equation of the given curve.

From the above it appears that, the incident rays being parallel, the reflecting curve can always be determined when the caustic can be rectified.

We see also from the nature of the connexion between the singular solutions and the ordinary primitives of differential equations, that the reflecting curve is in reality the envelope of

a system of parabolas whose axes are parallel to the direction of incident rays, whose foci are on the caustic, and whose parameters are subject to such a relation as makes that envelope to have contact of the second order with the curves out of whose differential elements it is formed. It is not merely an envelope, but an *osculating* envelope.

Analogy makes it evident that when the rays instead of being parallel issue from a given point, the reflecting curve is the osculating envelope of a system of ellipses, each of which has one focus at the radiant point, and the other on the arc of the caustic, the elliptic elements being further so conditioned as to render such osculations possible.

Lastly, it is plain that the problem of caustics in its direct and in its inverse form, as stated above, is in strict analogy with the direct and the inverse form of the problem of curvature, osculating parabolas and ellipses occupying the place and relation of osculating circles.

The above examples might also be treated by a remarkable method, the consideration of which will fitly close this Chapter.

### *Intrinsic Equation of a Curve.*

11. There are certain problems, the solution of which is much facilitated by the employment of what Dr Whewell has happily termed, the intrinsic equation of a curve, viz. the equation which expresses the relation between the length of an arc and the angle through which it bends, the latter being in more precise language the angle of deviation of the tangent from the tangent at the origin. These elements are called intrinsic because they are independent of any external lines of reference, and it will be noted that they form a system differing essentially from all systems of co-ordinates which begin by the defining of the position of a point, and in the application of which a curve is contemplated as a collection of points.

The conceptions of length and deviation upon which the above system is founded, might be replaced by the not less fundamental conceptions of length and curvature, the equation of the curve being then expressed in terms of its radius of curvature at the extremity of an arc and the length of that arc. Or,

in place of either of these systems, we might employ that which defines a curve by the relation which connects the curvature at any point with the deviation of the tangent. Of the three elements, length, curvature, and deviation, any two indeed will together constitute an equivalent system. Euler, in a particular class of problems, employed the combination last described. Here we shall select the one first mentioned, and shall borrow our chief illustrations of its use from the memoir of Dr Whewell (*Cambridge Philosophical Transactions*, Vol. VIII. p. 659, and Vol. IX. p. 150).

Representing by  $s$  the variable length of an arc the beginning of which is assumed as origin, and by  $\phi$  the corresponding angle of deviation, the intrinsic equation is of the form

$$s = f(\phi) \dots \dots \dots (35).$$

Thus in fig. 2,  $Sp = s$  and  $ATS = \phi$ .

From this equation the ordinary equation in rectangular co-ordinates may be found in the following manner. Still taking the beginning of the arc as origin, let the tangent at that point be taken as the axis of  $x$ , then will the element of the curve  $ds$  be inclined at an angle  $\phi$  to the axis  $x$ . Its projection on the axis of  $x$  will therefore be  $\cos \phi ds$ , and this being the differential element of the co-ordinate  $x$ , we have

$$dx = \cos \phi ds = \cos \phi f'(\phi) d\phi, \text{ by (35).}$$

$$\text{Hence} \quad x = \int \cos \phi f'(\phi) d\phi \dots \dots \dots (36),$$

and by symmetry

$$y = \int \sin \phi f'(\phi) d\phi \dots \dots \dots (37).$$

Between these equations after integration  $\phi$  must be eliminated; the result involving  $x, y$  and two arbitrary constants will be the equation required.

It is worth while to notice that the above result may be obtained independently of the consideration of a projection.

For since  $s = \int \left\{ 1 + \left( \frac{dy}{dx} \right)^2 \right\}^{\frac{1}{2}} dx$ , we have

$$\int \left\{ 1 + \left( \frac{dy}{dx} \right)^2 \right\}^{\frac{1}{2}} dx = f(\phi),$$

whence  $\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}^{\frac{1}{2}} dx = f'(\phi) d\phi \dots \dots \dots (38).$

But, since  $\frac{dy}{dx} = \tan \phi$ , the above becomes

$$\begin{aligned} \sec \phi dx &= f'(\phi) d\phi, \\ dx &= \cos \phi f'(\phi) d\phi, \\ x &= \int \cos \phi f'(\phi) d\phi, \end{aligned}$$

and in like manner employing for  $s$  the equivalent formula  $s = \int \left\{1 + \left(\frac{dx}{dy}\right)^2\right\}^{\frac{1}{2}} dy$ , we find

$$y = \int \sin \phi f'(\phi) d\phi,$$

which agree with the previous expressions.

Another consequence should also be noted. From (38) we have  $\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}^{\frac{1}{2}} = f'(\phi) \frac{d\phi}{dx}$ .

But  $\frac{d\phi}{dx} = \frac{d}{dx} \tan^{-1} \left(\frac{dy}{dx}\right) = \frac{\frac{d^2y}{dx^2}}{1 + \left(\frac{dy}{dx}\right)^2}$ , whence

$$\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}^{\frac{1}{2}} = f'(\phi) \frac{\frac{d^2y}{dx^2}}{1 + \left(\frac{dy}{dx}\right)^2}.$$

Therefore  $\frac{\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}^{\frac{3}{2}}}{\frac{d^2y}{dx^2}} = f'(\phi).$

Now the first member being the expression for the radius of curvature  $\rho$  of the given curve, we have

$$\rho = f'(\phi) \dots \dots \dots (39).$$

Thus the radius of curvature is determined.

12. *Given the ordinary, to deduce the intrinsic equation of a curve.*

The values of  $s$  and  $\phi$  having been first expressed in terms of the co-ordinates, it only remains to eliminate those co-ordinates between the two equations thus formed and the equation given.

Ex. To determine the intrinsic equation of the equiangular spiral.

The polar equation of the curve being  $r = C\epsilon^{m\theta}$ , the arc  $s$  beginning from  $\theta = 0$  is, by ordinary integration, found to be

$$s = C \frac{(m^2 + 1)^{\frac{1}{2}}}{m} (\epsilon^{m\theta} - 1).$$

Again, as the curve cuts all its radii at the same angles the deflection of the arc between two radii vectores is equal to the angle between the radii themselves. Hence the deflection of the arc beginning with  $\theta = 0$  is measured by  $\theta$ . Therefore  $\phi = \theta$ , and the intrinsic equation becomes

$$s = C \frac{(m^2 + 1)^{\frac{1}{2}}}{m} (\epsilon^{m\phi} - 1).$$

From this it appears that any intrinsic equation of the form

$$s = a (\epsilon^{m\phi} - 1) \dots \dots \dots (40)$$

will represent an equiangular spiral.

*Given the intrinsic equation of a curve, to deduce that of its evolute.*

Considering the given curve as formed by the unwinding of a string from its evolute, any arc of the former may be said to *correspond* to that arc of the latter by the unwinding of the string from which it is formed. Thus if  $s'$ ,  $\phi'$  represent elements of the evolute corresponding to  $s$ ,  $\phi$  in the given curve, then the origin of  $s'$  is that point of the evolute whose tangent forms the radius of curvature at the origin of  $s$ .

This premised, it is evident that we shall have

$$\phi' = \phi.$$

For the extreme differential elements of the arc of the evolute are respectively perpendicular to the corresponding extreme differential elements of an arc of the given curve. Hence the inclination of the former being equal to that of the latter, the value of  $\phi$  is the same for both.

Secondly, any arc of the evolute is by a known property equal to the difference of the radii of curvature of the extremities of the corresponding arc of the given curve. Hence if  $\rho_0$  represent the radius of curvature at the origin of the given curve, we shall have

$$s' = \rho - \rho_0 = f'(\phi) - f'(0), \text{ by (39),}$$

and, substituting  $\phi'$  for  $\phi$ ,

$$s' = f'(\phi') - f'(0).$$

Dropping the accents, we may therefore affirm that if the intrinsic equation of a curve is  $s = f(\phi)$ , that of its evolute will be  $s = f'(\phi) - f'(0)$ .

Ex. The intrinsic equation of the logarithmic spiral is  $s = a(\epsilon^{m\phi} - 1)$ . Hence that of its evolute is

$$\begin{aligned} s &= ma\epsilon^{m\phi} - ma \\ &= ma(\epsilon^{m\phi} - 1), \end{aligned}$$

which also denotes a logarithmic spiral.

Given the intrinsic equation of a curve in the form  $s = f(\phi)$  wherein  $f(\phi)$  vanishing with  $\phi$  is supposed capable of expansion in the form

$$f(\phi) = A_1\phi + A_2\phi^2 + A_3\phi^3 + \&c. \dots\dots\dots(41),$$

required the general intrinsic equation of the involute.

As to any curve there belong an infinite number of involutes depending on the different values given to that initial tangent to the curve which forms the initial radius of curvature of the involute, we shall represent the arbitrary value of that initial tangent by  $C$ .

Now if  $s = F(\phi)$  be the intrinsic equation of the involute, we have by the last proposition

$$F'(\phi) - F'(0) = f(\phi).$$

But  $F'(0)$ , being the initial radius of the curvature of the involute, is equal to  $C$ . Hence the above equation may be expressed in the form

$$\frac{dF(\phi)}{d\phi} = f(\phi) + C,$$

whence

$$\begin{aligned} F(\phi) &= \int f(\phi) d\phi + C\phi + C' \\ &= \frac{A_1\phi^2}{2} + \frac{A_2\phi^3}{3} \dots + C\phi + C'. \end{aligned}$$

Hence  $F(\phi)$  vanishing with  $\phi$ , we must have  $C' = 0$ . Thus the intrinsic equation of the involute, under the condition that its initial radius of curvature is  $\alpha$ , will be

$$s = \int f(\phi) d\phi + \alpha\phi \dots \dots \dots (42).$$

If, for distinction's sake, we represent the arc of the involute by  $s'$ , the equation may be expressed in the form

$$s' = \int (\alpha + s) d\phi \dots \dots \dots (43).$$

It is to be remembered that the lower limit of the integral is 0.

The following proposition from the memoir of Dr Whewell referred to, will illustrate the application of the above theorems.

Let any curve be evolved, and the involute evolved, and the involute of that evolved, beginning each evolution from the commencement of the curve last formed, and with a "rectilineal tail" which is of constant length for all. The curves tend continually to the form of the equiangular spiral.

Let  $s, s', s'', \&c.$  be the successive curves,  $\phi$  the angle which is the same for all, and let the tails represented in fig. 3, by  $AA', A'A'', A''A''', \&c.$  be each equal to  $\alpha$ .

Then representing the equation of the given curve by  $s = f(\phi)$ , we have for the first involute the equation

$$s' = \int (\alpha + s) d\phi = \alpha\phi + \int f(\phi) d\phi,$$

$$s'' = \int (\alpha + s') d\phi = \alpha\phi + \frac{\alpha\phi^2}{1.2} + \iint f(\phi) d\phi^2,$$

$$s''' = \int (\alpha + s'') d\phi = \alpha\phi + \frac{\alpha\phi^2}{1.2} + \frac{\alpha\phi^3}{1.2.3} + \iiint f(\phi) d\phi^3,$$

and in general

$$s^{(n)} = \alpha\phi + \frac{\alpha\phi^2}{1.2} + \frac{\alpha\phi^3}{1.2.3} \cdots + \frac{\alpha\phi^n}{1.2\dots n} + \int^n f(\phi) d\phi^n \dots (44).$$

Now giving to  $f(\phi)$  the form (41), we have

$$\int^n f(\phi) d\phi^n = \frac{A_1\phi^{n+1}}{1.2\dots(n+1)} + \frac{A_2\phi^{n+2}}{1.2\dots(n+2)} + \&c.$$

We see then that the first  $n$  terms of the expression for  $s^{(n)}$  in terms of  $\phi$  are unaffected by the form of the function  $f(\phi)$ , while those which remain are affected with coefficients which tend to 0. Thus the limiting form of (44) becomes

$$\begin{aligned} s^{(n)} &= \alpha\phi + \frac{\alpha\phi^2}{1.2} + \frac{\alpha\phi^3}{1.2.3} \cdots + \&c. \\ &= \alpha(\epsilon^\phi - 1) \dots\dots\dots (45). \end{aligned}$$

Now this is the equation of an equiangular spiral.

## EXERCISES.

1. Determine the curve whose subtangent varies as the abscissa.
2. Determine the curve whose normal varies as the square of the ordinate.
3. Shew that the curve in which the radius of curvature varies as the cube of the normal is a conic section.

4. Find a curve in which the length of the arc is in a constant ratio to the intercept cut off by the tangent from the axis of  $x$ .

5. Shew that the above is a particular case of curves of pursuit.

6. Find the orthogonal trajectory of a system of circles touching a given straight line in a given point.

7. Find the orthogonal trajectory of the system of ellipses defined by the equation  $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ ,  $b$  being the variable parameter.

8. Find the equation referred to polar co-ordinates of the curve in which the radius vector is equal to  $n$  times the length of the portion of the tangent intercepted between the point of contact and a straight line drawn from the pole to meet the tangent at a given angle.

9. Required the form of a pendant in Gothic architecture supposed to be a solid of revolution, such that the weight to be supported by each horizontal section shall be proportional to the area of that section.

10. Required the curve in which  $s = ax^2$ .

11. A curve is defined by this property; *viz.* that the radius of curvature at any point is a given multiple ( $n$ ) of the portion of the normal intercepted between the point and the axis of abscissæ; prove that the length of any portion of the curve may be finitely expressed in terms of the ordinates of its extremities. (*Cambridge Problems*, 1849.)

12. Find a differential equation of the first order of the curve whose radius of curvature is equal to  $n$  times the normal, and shew that this is always integrable in finite terms if  $n$  be an integer.

13. Shew that if  $n = 2$  the curve is a cycloid, if  $n = 1$  a circle, if  $n = -1$  a catenary.

14. The curve whose polar equation is  $r^m \cos m\theta = a^m$  rolls on a fixed straight line. Assuming that straight line as the

axis of  $x$ , shew that the locus of the curve described by the pole of the rolling curve will have for its equation

$$dx = \left\{ \left( \frac{y}{a} \right)^{\frac{2m}{1-m}} - 1 \right\}^{-\frac{1}{2}} dy.$$

(Frenet, *Recueil d'Exercices sur le Calcul Infinitésimal*.)

NOTE. To solve problems like the above, we observe that if  $RTS$ , Fig. 4, represent the given curve rolling on the given line  $OX$ , and  $APC$  the curve described by the pole  $P$ , then taking  $OX$  for the axis of  $x$ , and putting  $OM = x$ ,  $MP = y$ , the straight line  $PT$  joining that pole with the point of contact will be a radius vector of the given curve, but a normal of the described curve. Hence

$$r = y \sqrt{1 + \left( \frac{dy}{dx} \right)^2} \dots\dots\dots (a).$$

Again,  $PM$  is the perpendicular let fall from the pole upon the tangent of the given curve, but the ordinate  $y$  of the required curve. Hence

$$\frac{r^2 d\theta}{\sqrt{\{dr^2 + r^2 d\theta^2\}}} = y \dots\dots\dots (b).$$

By means of (a), (b), and the equation of the given curve, eliminating  $r$  and  $\theta$ , we obtain the differential equation of the curve sought.

15. In the particular case of  $m = \frac{1}{2}$  the rolling curve will be a parabola, the pole its focus, and the described curve a catenary.

16. If  $m = 2$ , the rolling curve is an equilateral hyperbola, the pole its centre, and the described curve an elastica.

## CHAPTER XII.

### ORDINARY DIFFERENTIAL EQUATIONS WITH MORE THAN TWO VARIABLES.

1. THE class of equations which we shall first consider in this Chapter, is represented by the typical form,

$$Pdx + Qdy + Rdz = 0 \dots\dots\dots(1),$$

$P$ ,  $Q$  and  $R$  being functions of the variables  $x$ ,  $y$ ,  $z$ ; and it is usually termed a total differential equation of the first order with three variables.

Possibly the first observation suggested by the examination of this form will be, that it does not answer to the definition of a differential equation, as the expression of a relation involving differential coefficients, Chap. I. And certainly it does not exhibit their notation. If, however, we attempt to attach a meaning to the general form (1), we shall perceive that the idea of a limit is involved essentially. And if we study its origin, we shall see that this idea may be expressed, here as elsewhere, in the language of differential coefficients.

For (1) is not understood as implying simply that the expression,

$$P\Delta x + Q\Delta y + R\Delta z \dots\dots\dots(2),$$

approaches to the value 0 when the increments  $\Delta x$ ,  $\Delta y$ ,  $\Delta z$  approach that value, true though it be that the vanishing of the increments causes that expression to vanish with them. But what (1) is always understood to express is, that in the approach to the limiting state, (2) tends to vanish in consequence of the *ratios* which the increments  $\Delta x$ ,  $\Delta y$ ,  $\Delta z$  tend to assume; it is, that if we represent (2) in any of the equivalent forms

$$\frac{P\Delta x + Q\Delta y + R\Delta z}{\Delta x} \Delta x, \quad \frac{P\Delta x + Q\Delta y + R\Delta z}{\Delta y} \Delta y, \quad \&c.$$

the limit of the ratio expressed by the first factor of each is 0. And the problem of the integration of (1), is that of the discovery

of the possible relation or relations among the primitive variables which will secure this result, supposing  $\Delta x$ ,  $\Delta y$ ,  $\Delta z$  to be so restricted as to preserve such relations unviolated.

Now whether the primitive variables are connected by *one* equation or by *two* simultaneous equations (we cannot suppose them connected by three equations without making them cease to be variable), the relation (1) is fully expressible in the language of differential coefficients. If there exist one primitive relation which, as we shall hereafter see, can only happen under particular circumstances, then

$$dz = \frac{dz}{dx} dx + \frac{dz}{dy} dy,$$

while (1) is presentable in the form

$$dz = -\frac{P}{R} dx - \frac{Q}{R} dy.$$

Hence, since  $dx$  and  $dy$  are independent, we have

$$\frac{dz}{dx} = -\frac{P}{R}, \quad \frac{dz}{dy} = -\frac{Q}{R} \dots\dots\dots (3),$$

a system which in the supposed case is equivalent to (1). On the other hand if, as will usually happen, two simultaneous equations connect the primitive variables, *e.g.*

$$\phi(x, y, z) = 0, \quad \psi(x, y, z) = 0 \dots\dots\dots (4),$$

then, since we have

$$\begin{aligned} \frac{d\phi}{dx} dx + \frac{d\phi}{dy} dy + \frac{d\phi}{dz} dz &= 0, \\ \frac{d\psi}{dx} dx + \frac{d\psi}{dy} dy + \frac{d\psi}{dz} dz &= 0, \end{aligned}$$

the elimination of  $dx$ ,  $dy$ ,  $dz$  between these and the original equation gives

$$\begin{aligned} P \left( \frac{d\phi}{dy} \frac{d\psi}{dz} - \frac{d\phi}{dz} \frac{d\psi}{dy} \right) + Q \left( \frac{d\phi}{dz} \frac{d\psi}{dx} - \frac{d\phi}{dx} \frac{d\psi}{dz} \right) \\ + R \left( \frac{d\phi}{dx} \frac{d\psi}{dy} - \frac{d\phi}{dy} \frac{d\psi}{dx} \right) = 0 \dots\dots\dots (5), \end{aligned}$$

a result which is equivalent to (1), but is expressed in the language of partial differential coefficients. As it constitutes but a single relation between two unknown functions  $\phi$  and  $\psi$ , one of the two may be considered arbitrary, and a particular form being given to it, we should have a partial differential equation for determining the other.

We propose indeed to discuss the equation (1) under its actual form, but it is not unimportant to shew that it constitutes no real exception to the definition of a differential equation. Treated by the methods proper to partial differential equations, the forms (3) and (5) lead to the same solutions as those investigated in this Chapter.

2. The foregoing remarks admit of geometrical illustrations.

If  $x, y, z$  and  $x + \Delta x, y + \Delta y, z + \Delta z$  are the co-ordinates of two points, the value of the expression  $P\Delta x + Q\Delta y + R\Delta z$ , where  $P, Q, R$  are given functions of  $x, y, z$ , will depend solely upon the positions of the points.

If we suppose the second point to approach the first *along any path*, the value of the above expression will approach to 0, in consequence of the quantities  $\Delta x, \Delta y, \Delta z$  approaching to 0, and independently of the *ratios* which they assume in vanishing. But this is not in accordance with the understood meaning of the equation (1).

The increments therefore not being independent, either they are connected by one relation, in which case one point being given the other must lie on the surface which that relation determines, and its approach to the first must be made along that surface, but is in no other way restricted; or the increments are connected by two relations, and then, the first point being given, the second must be on the line determined by those relations, and its approach to the first must be made along that line, and therefore in a definite path.

3. These considerations suggest to us the following questions for analysis, viz.:

1st. Under what circumstances is the solution of the equation  $Pdx + Qdy + Rdz = 0$  expressed by a single relation between the primitive variables—a relation which with the

arbitrary constant of integration will represent a family of surfaces ;—and how is such a relation to be determined ?

2ndly. How is the solution to be obtained when the above condition is not satisfied ?

These questions we shall next consider.

*The equation  $Pdx + Qdy + Rdz = 0$ , derivable from a single primitive.*

From the given equation, we have

$$dz = -\frac{P}{R} dx - \frac{Q}{R} dy \dots\dots\dots (6).$$

But the existence of a single primitive involves the supposition that  $z$  is a function of  $x$  and  $y$ , and therefore that we have

$$\frac{dz}{dx} = -\frac{P}{R}, \quad \frac{dz}{dy} = -\frac{Q}{R} \dots\dots\dots (7).$$

Hence, if  $\frac{P}{R}$  and  $\frac{Q}{R}$  do not contain  $z$ , we have, by the property of differential coefficients,

$$\frac{d}{dy} \frac{P}{R} = \frac{d}{dx} \frac{Q}{R}.$$

Should however  $\frac{P}{R}$  and  $\frac{Q}{R}$  both or either of them contain  $z$ , then, because we can still regard them as *ultimately* functions of  $x$  and  $y$ , for  $z$  is such by hypothesis, we must change the above into

$$\frac{d}{dy} \frac{P}{R} + \frac{dz}{dy} \frac{d}{dz} \frac{P}{R} = \frac{d}{dx} \frac{Q}{R} + \frac{dz}{dx} \frac{d}{dz} \frac{Q}{R}.$$

Lastly, substituting here for  $\frac{dz}{dy}$  and  $\frac{dz}{dx}$  their values given in (7), effecting the differentiations, and reducing, we have

$$P \left( \frac{dQ}{dz} - \frac{dR}{dy} \right) + Q \left( \frac{dR}{dx} - \frac{dP}{dz} \right) + R \left( \frac{dP}{dy} - \frac{dQ}{dx} \right) = 0 \dots\dots\dots (8),$$

an equation of condition which, when identically satisfied,

indicates that the proposed equation admits of a single primitive.

4. *To deduce the complete primitive of the differential equation  $Pdx + Qdy + Rdz = 0$  when the equation of condition (8) is satisfied.*

The supposed primitive involving all the variables  $x, y, z$ , it is evident that if we differentiate it on the hypothesis that  $z$  is constant, we shall arrive at a result equivalent to  $Pdx + Qdy = 0$ . It is also evident that if the primitive contained a function of  $z$  for one of its terms, that term, whatever the form of the function might be, would disappear in the differentiation.

Conversely then if we integrate the equation

$$Pdx + Qdy = 0 \dots\dots\dots (9),$$

regarding  $z$  as constant, and adding in the place of an arbitrary constant an arbitrary function of  $z$ , we shall arrive at a result which will necessarily *include* the complete primitive, and in which it will only remain necessary to determine what form must be given to the arbitrary function of  $z$ .

Thus, if the integrating factor of (9) be  $\mu$ , and if, assuming  $z$  constant, we write

$$\mu (Pdx + Qdy) = \frac{dV}{dx} dx + \frac{dV}{dy} dy,$$

then will the complete primitive be of the form

$$V = \phi(z) \dots\dots\dots (10),$$

in which it only remains to determine  $\phi(z)$ . And this will be done by differentiating with respect to all the variables and comparing with the given equation.

Differentiating (10) then with respect to  $x, y, z$ , and transposing, we have

$$\frac{dV}{dx} dx + \frac{dV}{dy} dy + \left\{ \frac{dV}{dz} - \frac{d\phi(z)}{dz} \right\} dz = 0,$$

whence

$$\mu (Pdx + Qdy) + \left\{ \frac{dV}{dz} - \frac{d\phi(z)}{dz} \right\} dz = 0.$$

Now by the given equation,  $Pdx + Qdy = -Rdz$ . Substituting, and rejecting the common factor  $dz$ , we have

$$-\mu R + \frac{dV}{dz} - \frac{d\phi(z)}{dz} = 0,$$

whence

$$\frac{d\phi(z)}{dz} = \frac{dV}{dz} - \mu R \dots\dots\dots(11),$$

the second member of which must, on the hypothesis that a single primitive exists, be reducible to a function of  $z$  by means of (10). The solution of the equation thus reduced will determine  $\phi(z)$ , the value of which substituted in (10) will give the complete primitive.

Although we are fully entitled to affirm that the equation determining  $\phi(z)$  must, whenever a single primitive exists, be reducible to a form not involving  $x$  and  $y$ ; it may be proper to verify this conclusion *a posteriori*.

Let us then inquire under what condition the function  $\frac{dV}{dz} - \mu R$  can be freed from both  $x$  and  $y$  by means of the equation  $V = \phi(z)$ . Evidently this can only be the case when  $\frac{dV}{dz} - \mu R$  and  $V$  are so related that, considered with respect to  $x$  and  $y$  alone, the one is a function of the other. Thus we have by the equation of condition (Prop. I. Chap. II.)

$$\frac{dV}{dx} \frac{d}{dy} \left( \frac{dV}{dz} - \mu R \right) - \frac{dV}{dy} \frac{d}{dx} \left( \frac{dV}{dz} - \mu R \right) = 0,$$

or

$$\begin{aligned} \frac{dV}{dx} \frac{d^2 V}{dz dy} - \frac{dV}{dy} \frac{d^2 V}{dz dx} + \mu \left( \frac{dR}{dx} \frac{dV}{dy} - \frac{dR}{dy} \frac{dV}{dx} \right) \\ + R \left( \frac{dV}{dy} \frac{d\mu}{dx} - \frac{dV}{dx} \frac{d\mu}{dy} \right) = 0 \dots\dots(12). \end{aligned}$$

Now since  $\frac{dV}{dx} = \mu P$ ,  $\frac{dV}{dy} = \mu Q$ , we have

$$\begin{aligned}\frac{dV}{dx} \frac{d^2V}{dzdy} - \frac{dV}{dy} \frac{d^2V}{dzdx} &= \mu P \frac{d}{dz} (\mu Q) - \mu Q \frac{d}{dz} (\mu P) \\ &= \mu^2 \left( P \frac{dQ}{dz} - Q \frac{dP}{dz} \right) \dots\dots\dots(13).\end{aligned}$$

Thus also

$$\mu \left( \frac{dR}{dx} \frac{dV}{dy} - \frac{dR}{dy} \frac{dV}{dx} \right) = \mu^2 \left( Q \frac{dR}{dx} - P \frac{dR}{dy} \right) \dots\dots(14).$$

Lastly,

$$R \left( \frac{dV}{dy} \frac{d\mu}{dx} - \frac{dV}{dx} \frac{d\mu}{dy} \right) = \mu R \left( Q \frac{d\mu}{dx} - P \frac{d\mu}{dy} \right) \dots\dots\dots(15).$$

But since  $\mu$  is the integrating factor of  $Pdx + Qdy$  we have, by Chap. v. Art. 1,

$$Q \frac{d\mu}{dx} - P \frac{d\mu}{dy} = \mu \left( \frac{dP}{dy} - \frac{dQ}{dx} \right),$$

which reduces (15) to the form

$$R \left( \frac{dV}{dy} \frac{d\mu}{dx} - \frac{dV}{dx} \frac{d\mu}{dy} \right) = \mu^2 R \left( \frac{dP}{dy} - \frac{dQ}{dx} \right) \dots\dots(16).$$

Substituting these values in (12) and rejecting the common factor  $\mu^2$ , there results

$$P \frac{dQ}{dz} - Q \frac{dP}{dz} + Q \frac{dR}{dx} - P \frac{dR}{dy} + R \frac{dP}{dy} - R \frac{dQ}{dx} = 0,$$

or

$$P \left( \frac{dQ}{dz} - \frac{dR}{dy} \right) + Q \left( \frac{dR}{dx} - \frac{dP}{dz} \right) + R \left( \frac{dP}{dy} - \frac{dQ}{dx} \right) = 0 \dots(17);$$

and this is identical with the equation of condition (8). The conclusion is therefore established.

It follows also that it is not necessary in any proposed case to apply directly the above equation of condition. It is *implicitly* involved in the very process of solution.

5. The results of the above investigation are contained in the following Rule.

**RULE.** *Integrate the proposed equation on the hypothesis that one of the variables is constant and its differential therefore equal to 0, adding an arbitrary function of that variable in the place of an arbitrary constant. Then differentiating with respect to all the variables, determine the arbitrary function by the condition that the result of such differentiation shall be equivalent to the equation given. The equation expressing such condition will, if a single primitive exist, be reducible by previous results to a form in which no other variable than the one involved in the arbitrary function will remain.*

**Ex. 1.** Given  $(y + a)^2 dx + zdy - (y + a) dz = 0$ .

Here  $P = (y + a)^2$ ,  $Q = z$ ,  $R = -y - a$ , values which identically satisfy the condition (8). The equation therefore admits of a single complete primitive.

Regarding  $z$  as constant we have first to integrate the equation

$$(y + a)^2 dx + zdy = 0.$$

Dividing by  $(y + a)^2$ , we have

$$dx + \frac{zdy}{(y + a)^2} = 0,$$

the solution of which is

$$x - \frac{z}{y + a} = \phi(z),$$

$\phi(z)$  being an arbitrary function of  $z$  introduced in the place of an arbitrary constant.

Now, differentiating with respect to all the variables, we have

$$dx + \frac{z}{(y + a)^2} dy - \left\{ \frac{1}{y + a} + \frac{d\phi(z)}{dz} \right\} dz = 0,$$

$$\text{or} \quad (y + a)^2 dx + zdy - \left\{ y + a + (y + a)^2 \frac{d\phi(z)}{dz} \right\} dz = 0,$$

which agrees with the equation given, if we have

$$-(y + a) = - \left\{ y + a + (y + a)^2 \frac{d\phi(z)}{dz} \right\},$$

$$\text{or} \quad \frac{d\phi(z)}{dz} = 0.$$

Here then  $\phi(z) = c$  and the complete primitive is

$$x - \frac{z}{y+a} = c \dots\dots\dots (a).$$

If we commence by regarding  $y$  as constant we obtain by a first integration

$$z - (y+a)x = \phi(y),$$

whence, differentiating and comparing with the given equation,

$$x + \frac{d\phi(y)}{dy} = \frac{z}{y+a}.$$

This equation involves both  $x$  and  $y$ , but it is reducible by the previous one to the form

$$\frac{d\phi(y)}{dy} = \frac{\phi(y)}{y+a},$$

or

$$\frac{d\phi(y)}{\phi(y)} = \frac{dy}{y+a},$$

of which the integral may be expressed in the form

$$\phi(y) = b(y+a),$$

$b$  being an arbitrary constant. Hence, finally,

$$\begin{aligned} z &= (y+a)x + b(y+a) \\ &= (y+a)(x+b), \end{aligned}$$

and this is equivalent to the former result (a).

Ex. 2. Given  $zdz + (x-a)dx = \{h^2 - z^2 - (x-a)^2\}^{\frac{1}{2}} dy$ .

Integrating as if  $y$  were constant we have

$$z^2 + (x-a)^2 = \phi(y) \dots\dots\dots (a).$$

Differentiating and comparing with the given equation,

$$\begin{aligned} \frac{1}{2} \frac{d\phi(y)}{dy} &= \{h^2 - z^2 - (x-a)^2\}^{\frac{1}{2}} \\ &= \{h^2 - \phi(y)\}^{\frac{1}{2}}, \text{ by } (a). \end{aligned}$$

Hence

$$\frac{-d\phi(y)}{2\{h^2 - \phi(y)\}^{\frac{1}{2}}} = -dy.$$

Therefore integrating

$$\{h^2 - \phi(y)\}^{\frac{1}{2}} = -y + b,$$

$b$  being an arbitrary constant. Hence determining  $\phi(y)$ , and substituting in (a), we have finally

$$z^2 + (x - a)^2 + (y - b)^2 = h^2,$$

where  $b$  is arbitrary.

### *Homogeneous Equations.*

6. When the equation  $Pdx + Qdy + Rdz = 0$  is homogeneous with respect to  $x, y, z$ , its solution will be facilitated by a transformation similar to that employed for homogeneous equations with two variables.

Assuming  $x = uz$ ,  $y = vz$ , we obtain by substitution a result of the form

$$L \frac{dz}{z} = Mdu + Ndv \dots \dots \dots (18).$$

If  $L$  be equal to 0 this simply gives

$$Mdu + Ndv = 0,$$

which can always be made integrable by a factor. If  $L$  be not equal to 0 we have

$$\frac{dz}{z} = \frac{M}{L} du + \frac{N}{L} dv;$$

and here the first member being an exact differential the second will be such also if a complete primitive exist. After integration,  $u$  and  $v$  must be replaced by their values  $\frac{x}{z}$ ,  $\frac{y}{z}$ .

Ex. 3. Given  $(ay - bz) dx + (cz - ax) dy + (bx - cy) dz = 0$ .

This equation satisfies the equation of condition (8).

Assuming  $x = uz$ ,  $y = vz$ , it becomes simply

$$(av - b) du - (au - c) dv = 0,$$

or

$$\frac{du}{au - c} = \frac{dv}{av - b},$$

the solution of which is

$$\frac{au - c}{av - b} = C,$$

whence the complete primitive sought will be

$$\frac{ax - cz}{ay - bz} = C.$$

Ex. 4. Given

$$(y^2 + yz + z^2) dx + (x^2 + xz + z^2) dy + (x^2 + xy + y^2) dz = 0.$$

Assuming  $x = uz$ ,  $y = vz$ , we have on reduction

$$\frac{dz}{z} = - \frac{(v^2 + v + 1) du + (u^2 + u + 1) dv}{(u + v + 1)(uv + u + v)},$$

or 
$$\frac{dz}{z} = \frac{du + dv}{u + v + 1} - \frac{(v + 1) du + (u + 1) dv}{uv + u + v},$$

whence integrating

$$\log z = \log \frac{u + v + 1}{uv + u + v} + C.$$

Finally we have

$$\frac{xy + xz + yz}{x + y + z} = C',$$

for the complete primitive.

The last two equations might have been integrated without preliminary transformation. (Lacroix, Tom. II. pp. 507—510.)

### *Integrating factors.*

7. The equation  $Pdx + Qdy + Rdz = 0$  can also, when there exists a single complete primitive, be integrated by means of a factor.

If  $\mu$  be that factor, then, since the expression

$$\mu Pdx + \mu Qdy + \mu Rdz$$

must be an exact differential, we must have

$$\frac{d(\mu Q)}{dz} = \frac{d(\mu R)}{dy}, \quad \frac{d(\mu R)}{dx} = \frac{d(\mu P)}{dz},$$

$$\frac{d(\mu P)}{dy} = \frac{d(\mu Q)}{dx},$$

equations to which we may give the forms

$$Q \frac{d\mu}{dz} - R \frac{d\mu}{dy} + \mu \left( \frac{dQ}{dz} - \frac{dR}{dy} \right) = 0,$$

$$R \frac{d\mu}{dx} - P \frac{d\mu}{dz} + \mu \left( \frac{dR}{dx} - \frac{dP}{dz} \right) = 0,$$

$$P \frac{d\mu}{dy} - Q \frac{d\mu}{dx} + \mu \left( \frac{dP}{dy} - \frac{dQ}{dx} \right) = 0.$$

Multiplying these equations by  $P$ ,  $Q$ , and  $R$ , respectively, adding, and dividing by  $\mu$ , we have

$$P \left( \frac{dQ}{dz} - \frac{dR}{dy} \right) + Q \left( \frac{dR}{dx} - \frac{dP}{dz} \right) + R \left( \frac{dP}{dy} - \frac{dQ}{dx} \right) = 0 \dots (19),$$

the same equation of condition which was before obtained.

When this equation is satisfied a particular form of the factor  $\mu$  will frequently suggest itself.

In Ex. 3 the functions  $\frac{1}{(ay - bz)^2}$ ,  $\frac{1}{(cz - ax)^2}$ ,  $\frac{1}{(bx - cy)^2}$  are integrating factors. In Ex. 4 the functions  $\frac{1}{(x + y + z)^2}$  and  $\frac{1}{(xy + xz + yz)^2}$  are integrating factors.

*Equations not derivable from a single primitive.*

8. To solve the equation  $Pdx + Qdy + Rdz = 0$ , when the equation of condition (8) is not satisfied.

In this case the solution consists of two simultaneous equations between  $x, y, z$ , one of which is perfectly arbitrary in form.

For representing an assumed arbitrary equation in the form

$$f(x, y, z) = 0 \dots\dots\dots (20),$$

and differentiating, we have

$$\frac{df(x, y, z)}{dx} dx + \frac{df(x, y, z)}{dy} dy + \frac{df(x, y, z)}{dz} dz = 0.$$

Now these two equations enabling us, when the form of  $f(x, y, z)$  is specified, to eliminate one of the variables and its differential, e. g.  $z$  and  $dz$ , from the equation given, permit us to reduce it to the form

$$Mdx + Ndy = 0,$$

$M$  and  $N$  being functions of  $x$  and  $y$ . Solving this, we obtain an equation involving an arbitrary constant, and this equation together with (20) will constitute a solution. By giving different forms to  $f(x, y, z)$  every possible solution may be obtained. What a solution thus found represents in geometrical construction is the drawing, on a particular surface, of a family of lines, each of which satisfies at every point the condition  $Pdx + Qdy + Rdz = 0$ . Now  $dx, dy, dz$  are proportional to the directing cosines of the tangent line. Hence the geometrical problem may be represented as that of drawing on a given surface a family of lines, in each of which the directing cosines  $\cos \phi, \cos \psi, \cos \chi$  at any point shall satisfy the condition

$$P \cos \phi + Q \cos \psi + R \cos \chi = 0 \dots\dots\dots (21).$$

Ex. Required the most general solution of the equation

$$x dx + y dy + c \left( 1 - \frac{x^2}{a^2} - \frac{y^2}{b^2} \right)^{\frac{1}{2}} dz = 0 \dots\dots\dots (a),$$

which is consistent with the assumption that it shall represent a series of lines traced upon the ellipsoid whose equation is

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1 \dots\dots\dots (b).$$

It will be found that (a) does not satisfy the equation of condition (8).

Differentiating (b), we have

$$\frac{x dx}{a^2} + \frac{y dy}{b^2} + \frac{z dz}{c^2} = 0,$$

whence

$$\begin{aligned} dz &= -\frac{c^2}{z} \left( \frac{x dx}{a^2} + \frac{y dy}{b^2} \right) \\ &= \frac{-c \left( \frac{x dx}{a^2} + \frac{y dy}{b^2} \right)}{\left( 1 - \frac{x^2}{a^2} - \frac{y^2}{b^2} \right)^{\frac{1}{2}}}, \end{aligned}$$

and this reduces (a) to

$$x dx + y dy - c^2 \left( \frac{x dx}{a^2} + \frac{y dy}{b^2} \right) = 0 \dots\dots\dots (c),$$

the integral of which is

$$\left( 1 - \frac{c^2}{a^2} \right) x^2 + \left( 1 - \frac{c^2}{b^2} \right) y^2 = C \dots\dots\dots (d),$$

indicating that the projections of the proposed family of lines will be a certain series of central conic sections.

If  $a = b = c = 1$  the proposed equation admits of a single primitive, viz.  $x^2 + y^2 + z^2 = 1$ . And any line traced on the surface of which this is the equation will satisfy the differential equation; for the equation (c) by which the lines are ordinarily determined is now reduced to an identity.

The above method of solution is due to Newton. Monge has however remarked that the general solution may be expressed by the equations (10) and (11) of Art. 4, viz. by the simultaneous system

$$V = \phi(z) \dots\dots\dots (22),$$

$$\frac{dV}{dz} - \mu R = \phi'(z) \dots\dots\dots (23),$$

where  $\mu$  is the integrating factor, and  $V$  the corresponding integral of the expression  $Pdx + Qdy$ . It is indeed shewn in

that Article that (22) does satisfy the differential equation provided that the condition (23) is satisfied. But there is no *practical* advantage in the employment of Monge's form. Applied to the problem of drawing on a given surface lines satisfying the condition expressed by the differential equation, it makes the determination of the arbitrary function  $\phi(z)$  itself dependent on the solution of a differential equation.

Thus in the example last considered we have, on giving to  $\mu$  the value 2,

$$V = x^2 + y^2, \quad R = c \left(1 - \frac{x^2}{a^2} - \frac{y^2}{b^2}\right)^{\frac{1}{2}},$$

so that the *general* solution assumes the form

$$\begin{aligned} x^2 + y^2 &= \phi(z) \\ -2c \left(1 - \frac{x^2}{a^2} - \frac{y^2}{b^2}\right)^{\frac{1}{2}} &= \phi'(z). \end{aligned}$$

To apply this to the problem of drawing lines satisfying the conditions of the problem on the ellipsoid

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1 \dots\dots\dots(e),$$

it is necessary from the above three equations to eliminate  $x$  and  $y$ . From the second and third which here suffice, we have

$$-2z = \phi'(z),$$

whence

$$\phi(z) = -z^2 + C.$$

Therefore

$$x^2 + y^2 + z^2 = C \dots\dots\dots(f).$$

The particular solution sought is therefore expressed by the equations (e) and (f), which are together equivalent to the previous solution expressed by (b) and (d).

*Total differential equations containing more than three variables.*

9. It will suffice to make a few observations on the equation with four variables

$$Pdx + Qdy + Rdz + Tdt = 0 \dots\dots\dots(24),$$

and to direct attention to the general analogy.

Writing the above equation in the form

$$dt = -\frac{P}{T}dx - \frac{Q}{T}dy - \frac{R}{T}dz \dots\dots\dots(25),$$

it is evident that, in order that it should be derivable from a single primitive, we must have

$$\left(\frac{d}{dx}\right)\frac{Q}{T} = \left(\frac{d}{dy}\right)\frac{P}{T}, \quad \left(\frac{d}{dy}\right)\frac{R}{T} = \left(\frac{d}{dz}\right)\frac{Q}{T}, \quad \left(\frac{d}{dz}\right)\frac{P}{T} = \left(\frac{d}{dx}\right)\frac{R}{T},$$

where  $\left(\frac{d}{dx}\right)$  refers to  $x$  not only as appearing independently, but also as implicitly involved in  $t$ ; and so on for the rest.

Effecting the differentiations, and substituting for  $\frac{dt}{dx}$ ,  $\frac{dt}{dy}$ ,  $\frac{dt}{dz}$  their values implied in (25), we have

$$\left. \begin{aligned} T\left(\frac{dQ}{dx} - \frac{dP}{dy}\right) + P\left(\frac{dT}{dy} - \frac{dQ}{dt}\right) + Q\left(\frac{dP}{dt} - \frac{dT}{dx}\right) &= 0 \\ T\left(\frac{dR}{dy} - \frac{dQ}{dz}\right) + Q\left(\frac{dT}{dz} - \frac{dR}{dt}\right) + R\left(\frac{dQ}{dt} - \frac{dT}{dy}\right) &= 0 \\ T\left(\frac{dP}{dz} - \frac{dR}{dx}\right) + R\left(\frac{dT}{dx} - \frac{dP}{dt}\right) + P\left(\frac{dR}{dt} - \frac{dT}{dz}\right) &= 0 \end{aligned} \right\} \dots\dots(26)$$

which are the equations of condition of existence of a single complete primitive.

It is evident from the symmetry of the problem that the equation

$$P\left(\frac{dQ}{dz} - \frac{dR}{dy}\right) + Q\left(\frac{dR}{dx} - \frac{dP}{dz}\right) + R\left(\frac{dP}{dy} - \frac{dQ}{dx}\right) = 0 \dots(27)$$

must also hold here. But this is not a new condition. It may be deduced from (26), by multiplying the respective equations of that system by  $R$ ,  $P$ , and  $Q$ , and adding the results.

It is obvious that when there exist  $n$  variables, the number of independent equations of condition is  $\frac{(n-1)(n-2)}{2}$ , being the number of ways of equating two partial differential coefficients in a system in which  $n-1$  are contained.

The solution of any such equation may be effected by an extension of the method adopted for equations with three variables. We must integrate as if all but two of the variables were constant, adding, in the place of an arbitrary constant, an arbitrary function of the variables which remain. This function we must determine by differentiating with respect to all the variables, and comparing with the equation given. If a single primitive exist, such determination will be possible. If a single primitive do not exist, we must, following the analogy of the corresponding case of three variables, endeavour to express the solution by a system of simultaneous equations. And such is indeed its general form. Pfaff, in a memoir published by the Berlin Academy 1814—15, has shewn that, according as the number of variables is  $2n$  or  $2n+1$ , the number of integral equations is  $n$  or  $n+1$  *at most*. His method, which is remarkable, consists of alternate integrations and transformations. For important commentaries and additions see Jacobi (*Werke*, Tom. I. p. 140), and Raabe (*Crelle*, Tom. XIV. p. 123).

Ex. Given  $(2x+y^2+2xy_2-y_1)dx+2xydy-xdy_1+x^2dy_2=0$ .

If we suppose the variables  $y_1, y_2$  constant, we have to integrate

$$(2x+y^2+2xy_2-y_1)dx+2xydy=0,$$

which, on substituting an arbitrary function of  $y_1, y_2$  represented by  $\phi$ , for an arbitrary constant, gives

$$x^2+xy^2+x^2y_2-xy_1=\phi.$$

Differentiating with respect to all the variables, we have

$$\begin{aligned} (2x+y^2+2xy_2-y_1)dx+2xydy-xdy_1+x^2dy_2 \\ = \frac{d\phi}{dy_1}dy_1+\frac{d\phi}{dy_2}dy_2. \end{aligned}$$

Comparing this with the given equation, we have

$$\frac{d\phi}{dy_1} dy_1 + \frac{d\phi}{dy_2} dy_2 = 0,$$

whence  $\phi = c$  and the solution is

$$x^2 + xy^2 + x^2y_2 - xy_1 = c \dots\dots\dots (a).$$

Had we begun by making  $x$  and  $y$  constant, we should have had as the result of the first integration,

$$x^2y_2 - xy_1 = \phi \dots\dots\dots (b),$$

$\phi$  denoting a function of  $x$  and  $y$ . Differentiating with respect to all the variables and comparing with the given equation, we should find

$$d\phi = -(2x + y^2) dx - 2xy dy,$$

whence  $\phi = -x^2 - xy^2 + c,$

the substitution of which in (b) reproduces the former solution (a).

*Equations of an order higher than the first.*

10. When an equation of the form

$$A dx^2 + B dy^2 + C dz^2 + 2D dy dz + 2E dx dz + 2F dx dy = 0 \dots (28)$$

is resolvable into two equations each of the form

$$P dx + Q dy + R dz = 0,$$

the solution of either of these obtained by previous methods, will be a particular solution of (28), and the two solutions taken disjunctively will constitute the complete solution, which is therefore expressed by the *product* of the equations of these solutions, each reduced to the form  $V = 0$ .

The condition under which (28) is resolvable as above, is expressed by the equation

$$ABC + 2DEF - AD^2 - BE^2 - CF^2 = 0 \dots\dots\dots (29).$$

This is shewn by solving (28) with respect to  $dx$ , and assuming the quantity under the radical to be a complete square.

Thus, the equation  $x^2 dx^2 + y^2 dy^2 - z^2 dz^2 + 2xy dx dy = 0$ , which will be found to satisfy the above condition, is resolvable into the two equations

$$x dx + y dy + z dz = 0, \quad x dx + y dy - z dz = 0,$$

$$\text{whence } x^2 + y^2 + z^2 = c \dots (a), \quad x^2 + y^2 - z^2 = c' \dots\dots (b).$$

Geometrically the solution is expressed by lines drawn in any manner on the surface, either of the sphere (a), or of the hyperboloid (b).

When the condition (29) is not satisfied, the proposed equation does not admit of a single primitive, or of any *disjunctive* system of primitives. But it does in general admit of a solution expressed by a system of *simultaneous* equations. Thus, if we integrate the equation  $dz^2 = m^2 (dx^2 + dy^2)$ , supposing  $x$  constant, we find  $z = my + C$ , or, replacing  $C$  by a function of  $x$ ,

$$z = my + \phi(x) \dots\dots\dots (c).$$

On substitution and integration, we find that this will satisfy the proposed equation if we have

$$2y = m \int \frac{dx}{\phi'(x)} - \frac{1}{m} \phi(x) + c \dots\dots\dots (d),$$

the system (c) (d) will therefore constitute a solution of the equation given. We enter not into the question whether it is the most general solution or not, proposing merely to exemplify the kind of solution of which the equation admits.

To this we may add that all equations which do not satisfy the conditions of integrability, though they may present themselves in the form of *ordinary*, have a far more intimate connexion with *partial* differential equations; and that this connexion affords the best clue to the solution of their theoretical difficulties.

## EXERCISES.

$$1. \quad \frac{dx}{x-a} + \frac{dy}{y-b} + \frac{dz}{z-c} = 0.$$

$$2. \quad (x-3y-z) dx + (2y-3x) dy + (z-x) dz = 0.$$

$$3. \quad (y+z) dx + (z+x) dy + (x+y) dz = 0.$$

$$4. \quad yz dx + zx dy + xy dz = 0.$$

$$5. \quad (y+z) dx + dy + dz = 0.$$

$$6. \quad ay^2z^2dx + bz^2x^2dy + cx^2y^2dz = 0.$$

$$7. \quad (x^2y - y^3 - y^2z) dx + (xy^2 - x^2z - x^3) dy + (xy^2 + x^2y) dz = 0.$$

$$8. \quad (2x^2 + 2xy + 2xz^2 + 1) dx + dy + 2zdz = 0.$$

$$9. \quad (2x + y^2 + 2xz) dx + 2xy dy - dw + x^2 dz = 0.$$

10. Is the equation  $(1+2m)x dx + y(1-x) dy + z dz = 0$  derivable from a single primitive of the form  $\phi(x, y, z) = c$ ?

11. Shew that any system of lines described on the surface of the sphere  $x^2 + y^2 + z^2 = r^2$ , and satisfying the above equation, would be projected on the plane  $xy$  in parabolas.

12. Shew that Monge's method would, if we integrate first with respect to  $x$  and  $z$ , present the solution of the equation of Ex. 10, in the form

$$(1+2m)x^2 + z^2 = \phi(y), \quad 2y(1-x) = -\phi'(y).$$

13. Applying this form to the problem of Ex. 11, form and solve the differential equation for the determination of  $\phi(y)$ , and shew that it leads to the result stated in that Example.

14. Find the equation of the projections of the same system of curves on the plane  $yz$ .

## CHAPTER XIII.

## SIMULTANEOUS DIFFERENTIAL EQUATIONS.

1. WE have hitherto considered only single differential equations. We have now to treat of systems of differential equations.

Of such by far the most important class is that in which one of the variables is independent and the others are dependent upon it, the number of equations in the system being equal to the number of dependent variables. Thus in the chief problem of physical astronomy—the problem of the motion of a system of material bodies abandoned to their mutual attractions—there is but one independent variable, the time; the dependent variables are the co-ordinates, which, varying with the time, determine the varying positions of the several members of the material system; while, lastly, the number of equations being equal to the number of co-ordinates involved, the dependence of the latter upon the time is made determinate.

Such a system of equations may properly be called a determinate system.

We propose in this Chapter to treat only of systems of equations of the above class. And in the first instance we shall speak of simultaneous differential equations of the first order and degree, beginning with particular examples, and proceeding to the consideration of their general theory.

*Particular Illustrations.*

2. The simplest class of examples is that in which the equations of the given system are separately integrable.

Ex. 1. Given  $l dx + m dy + n dz = 0$ ,  $x dx + y dy + z dz = 0$ .

Integrating separately, we have

$$lx + my + nz = c, \quad x^2 + y^2 + z^2 = c';$$

and these equations expressing the complete solution of the given system may be said to constitute the primitive system.

Another class of examples is that in which, while the equations of the given system are not all separately integrable, they admit of being so combined as to produce an equivalent system of equations which are separately integrable.

Ex. 2. Given  $\frac{dx}{dt} + \frac{2x}{t} = 1$ ,  $\frac{dy}{dt} = x + y + \frac{2x}{t} - 1$ .

Here the first equation alone is separately integrable, and gives

$$x = \frac{t}{3} + \frac{c}{t^2} \dots\dots\dots (a).$$

Also by addition of the given equations, we have

$$\frac{dx + dy}{dt} = x + y;$$

therefore  $\frac{dx + dy}{x + y} = dt,$

$$\log(x + y) = t + c' \dots\dots\dots (b).$$

The primitive system is therefore expressed by (a) and (b).

In both the above examples we see that the number of equations of the solution is equal to that of the equations of the system given, and that each equation of the solution involves a distinct arbitrary constant. And it is evident that this must be the case whenever we can combine the given equations into an equivalent system of integrable equations of the first order. But as we have not proved that such combination is possible, the following question becomes important, viz. what is the nature of the solution of a system of simultaneous equations of the first order and degree?

This question will be considered in the next section.

*General theory of simultaneous equations of the first order and degree.*

3. We shall seek first to establish the general theory of a system composed of two equations between three variables, and therefore of the form

$$\left. \begin{aligned} Pdx + Qdy + Rdz &= 0, \\ P'dx + Q'dy + R'dz &= 0, \end{aligned} \right\} \dots\dots\dots (1),$$

the coefficients  $P$ ,  $P'$ , &c. being functions of the variables, or constants.

We design to consider the above system first, and with the greater care, because there is scarcely any part of the general theory which it does not serve to exemplify.

PROP. *The solution of the system (1) can always be made to depend upon that of an ordinary differential equation of the second order between two of the primitive variables, and it always consists of two equations involving two arbitrary constants.*

By algebraic solution of the system (1) we have

$$dy = \frac{RP' - PR'}{QR' - RQ'} dx, \quad dz = \frac{PQ' - QP'}{QR' - RQ'} dx \dots\dots\dots (2).$$

As the coefficients of  $dx$  in the second members of these equations are functions of  $x, y, z$  we may express the reduced system in the form

$$dy = \phi(x, y, z) dx, \quad dz = \psi(x, y, z) dx,$$

whence, regarding  $x$  as independent variable,

$$\frac{dy}{dx} = \phi(x, y, z) \dots\dots\dots (3),$$

$$\frac{dz}{dx} = \psi(x, y, z) \dots\dots\dots (4).$$

Thus the given system enables us to express  $\frac{dy}{dx}$  and  $\frac{dz}{dx}$  by known functions of  $x, y, z$ .

Now differentiating (3), still on the assumption that  $x$  is the independent variable and representing for brevity  $\phi(x, y, z)$  by  $\phi$ ,  $\psi(x, y, z)$  by  $\psi$ , we have

$$\frac{d^2y}{dx^2} = \frac{d\phi}{dx} + \frac{d\phi}{dy} \frac{dy}{dx} + \frac{d\phi}{dz} \frac{dz}{dx},$$

or substituting for  $\frac{dz}{dx}$  its value given by (4),

$$\frac{d^2y}{dx^2} = \frac{d\phi}{dx} + \frac{d\phi}{dy} \frac{dy}{dx} + \psi \frac{d\phi}{dz} \dots\dots\dots (5).$$

This equation involves  $\frac{dy}{dx}$  and  $\frac{d^2y}{dx^2}$  together with the quantities  $\frac{d\phi}{dx}$ ,  $\frac{d\phi}{dy}$ ,  $\frac{d\phi}{dz}$  and  $\psi$ , which are known functions of  $x$ ,  $y$ , and  $z$ . Hence eliminating  $z$  by means of (3) we have a final equation involving  $\frac{dy}{dx}$ ,  $\frac{d^2y}{dx^2}$ ,  $x$ , and  $y$ . The complete primitive of this differential equation of the second order will enable us to express  $y$  as a function of  $x$  and two arbitrary constants. Suppose the value thus obtained for  $y$  to be

$$y = \chi(x, c_1, c_2) \dots\dots\dots (6).$$

Then we have by virtue of (3)

$$\phi(x, y, z) = \frac{d\chi(x, c_1, c_2)}{dx} \dots\dots\dots (7).$$

These two equations involving two arbitrary constants contain the complete solution of the system given.

4. It is important to observe that the system (2) may be expressed in the symmetrical form

$$\frac{dx}{QR' - RQ'} = \frac{dy}{RP' - PR'} = \frac{dz}{PQ' - QP'}.$$

If we represent the denominators of the above reduced system by  $X$ ,  $Y$ ,  $Z$ , it becomes

$$\frac{dx}{X} = \frac{dy}{Y} = \frac{dz}{Z} \dots\dots\dots (8).$$

This, then, may be regarded as the symmetrical form of a system composed of two differential equations of the first order.

Again, the complete solution of such a system, as is expressed by (6) and (7), consists of two equations connecting the variables  $x$ ,  $y$ ,  $z$  with two arbitrary constants. If we solve these equations with respect to the constants, the solution assumes the form

$$\phi_1(x, y, z) = c_1, \quad \phi_2(x, y, z) = c_2 \dots\dots\dots (9).$$

Thus a system of two differential equations of the first order may, without loss of generality, be presented in the symmetrical form (8), and its complete solution in the symmetrical form (9).

Ex. 1. Given

$$(5y + 9z) dx + dy + dz = 0, \quad (4y + 3z) dx + 2dy - dz = 0.$$

Here we find by algebraic solution

$$\frac{dy}{dx} = -3y - 4z \dots\dots\dots (a),$$

$$\frac{dz}{dx} = -2y - 5z \dots\dots\dots (b),$$

whence

$$\begin{aligned} \frac{d^2y}{dx^2} &= -3 \frac{dy}{dx} - 4 \frac{dz}{dx} \\ &= -3 \frac{dy}{dx} + 8y + 20z, \text{ by } (b). \end{aligned}$$

Eliminating  $z$  by (a), we have on reduction

$$\frac{d^2y}{dx^2} + 8 \frac{dy}{dx} + 7y = 0,$$

a linear equation with constant coefficients whose complete primitive is

$$y = C_1 e^{-x} + C_2 e^{-7x} \dots\dots\dots (c).$$

Equating the value of  $\frac{dy}{dx}$  hence determined with that given in (a) we have

$$3y + 4z = C_1 e^{-x} + 7 C_2 e^{-7x} \dots\dots\dots (d).$$

The complete solution is therefore expressed by (c) and (d).

Theoretically it is of no consequence which of the primitive variables we assume as independent. But practically the question is of some importance as affecting the character of the final differential equation.

Ex. 2. Given  $\frac{dx}{dt} - 3x + y = 0, \quad \frac{dy}{dt} - x - y = 0.$

Differentiating the first equation we have

$$\frac{d^2x}{dt^2} - 3 \frac{dx}{dt} + \frac{dy}{dt} = 0,$$

from which eliminating  $\frac{dy}{dt}$  by the second equation we have

$$\frac{d^2x}{dt^2} - 3 \frac{dx}{dt} + x + y = 0.$$

Hence eliminating  $y$  by the first equation

$$\frac{d^2x}{dt^2} - 4 \frac{dx}{dt} + 4x = 0.$$

Integrating

$$x = (C + C't) \epsilon^{2t},$$

and this value of  $x$  substituted in the first equation gives

$$y = (C - C' + C't) \epsilon^{2t}.$$

The last two equations constitute the primitive system.

We choose next an example in which the given system involves functions of the independent variable in the second members.

Ex. 3. Given  $\frac{dx}{dt} + 5x - 2y = \epsilon^t, \quad \frac{dy}{dt} - x + 6y = \epsilon^{2t}.$

Here, differentiating the first equation, we have

$$\frac{d^2x}{dt^2} + 5 \frac{dx}{dt} - 2 \frac{dy}{dt} = \epsilon^t.$$

Eliminating  $\frac{dy}{dt}$  by the second equation of the given system, we have

$$\frac{d^2x}{dt^2} + 5 \frac{dx}{dt} - 2x + 12y = \epsilon^t + 2\epsilon^{2t}.$$

And, eliminating  $y$  by means of the first equation of the system,

$$\frac{d^2x}{dt^2} + 11 \frac{dx}{dt} + 28x = 7\epsilon^t + 2\epsilon^{2t},$$

a linear differential equation of the second order whose solution is

$$x = C_1 \epsilon^{-4t} + C_2 \epsilon^{-7t} + \frac{7}{40} \epsilon^t + \frac{1}{27} \epsilon^{2t}.$$

Hence, by the first of the given equations,

$$2y - 5x + \epsilon^t = -4C_1 \epsilon^{-4t} - 7C_2 \epsilon^{-7t} + \frac{7}{40} \epsilon^t + \frac{2}{27} \epsilon^{2t}.$$

The last two equations are the complete primitives of the system given.

5. The above theory may be extended to all systems which are composed of  $n$  differential equations of the first order and degree connecting  $n + 1$  variables.

Assume  $x$  (independent) and  $x_1, x_2, \dots, x_n$  (dependent) as the variables of the system. Then there exist  $n$  differential equations of the form

$$Pdx + P_1dx_1 + P_2dx_2 \dots + P_ndx_n = 0 \dots \dots (10),$$

$P, P_1$ , &c. being functions of the variables. These equations exactly suffice to determine the ratios of the differentials  $dx, dx_1, \dots, dx_n$ , and thus assume the symmetrical form

$$\frac{dx}{X} = \frac{dx_1}{X_1} = \frac{dx_2}{X_2} \dots = \frac{dx_n}{X_n} \dots \dots \dots (11),$$

$X, X_1$ , &c. being determinate functions of the variables.

This premised, the solution of the system (11) depends upon the solution of a single differential equation of the  $n^{\text{th}}$  order connecting two of the variables.

Let us select for the two  $x$  and  $x_1$ .

Now (11) gives

$$\frac{dx_1}{dx} = \frac{X_1}{X}, \quad \frac{dx_2}{dx} = \frac{X_2}{X}, \quad \dots \quad \frac{dx_n}{dx} = \frac{X_n}{X} \dots \dots \dots (12).$$

Differentiate the first of these  $n - 1$  times in succession, regarding  $x$  as independent variable and continually substituting for  $\frac{dx_2}{dx}, \dots, \frac{dx_n}{dx}$  their values as given by the  $n - 1$  last equations of the above system. We thus obtain, including the equation operated upon,  $n$  equations connecting

$$\frac{dx_1}{dx}, \quad \frac{d^2x_1}{dx^2} \dots \frac{d^nx_1}{dx^n}$$

with the primitive variables and therefore enabling us, 1st, to express the above  $n$  differential coefficients in terms of those variables, 2ndly, by elimination of the  $n - 1$  variables,  $x_2, x_3, \dots, x_n$ , to deduce a single equation of the form

$$F\left(x, x_1, \frac{dx_1}{dx}, \frac{d^2x_1}{dx^2} \dots \frac{d^nx_1}{dx^n}\right) = 0 \dots \dots \dots (13).$$

comply the same object. Neither is it always necessary to proceed to differential equations of an order higher than the first. This point will be illustrated in the following sections.

*Linear equations of the first order with constant coefficients.*

6. The characters here mentioned have reference only to the dependent variables which are the true unknown quantities of the system. Thus the equation

$$a \frac{dx}{dt} + b \frac{dy}{dt} + cx + ey = \phi(t)$$

would be described as linear and with constant coefficients.

The solution of any system of  $n$  such equations is by the foregoing general method reducible to that of an ordinary linear differential equation of the  $n^{\text{th}}$  order with constant coefficients. And this method is in the two following respects the best of all, viz. 1st, because of its fundamental character, 2ndly, because it leads directly to the expression of the values of the dependent variables.

The solution of such a system may however also be effected by the method of indeterminate multipliers, and this we propose here to exemplify. Its advantage is that it generally presents the equations of the solution under a common type, so that their discovery is made to depend upon the discovery of a single general form.

Ex. Given  $\frac{dx}{dt} = ax + by + c, \quad \frac{dy}{dt} = a'x + b'y + c'.$

Multiplying the second equation by an indeterminate quantity  $m$ , and adding to the first, we have

$$\begin{aligned} \frac{dx + mdy}{dt} &= (a + ma')x + (b + mb')y + c + mc' \\ &= (a + ma') \left( x + \frac{b + mb'}{a + ma'} y + \frac{c + mc'}{a + ma'} \right) \\ &= (a + ma') \left( x + my + \frac{c + mc'}{a + ma'} \right) \dots\dots\dots(a), \end{aligned}$$

provided that we determine  $m$  so as to satisfy the condition

$$m = \frac{b + mb'}{a + ma'},$$

or 
$$a'm^2 + (a - b')m - b = 0 \dots\dots\dots(b).$$

Now (a) gives

$$\frac{dx + mdy}{x + my + \frac{c + mc'}{a + ma'}} = (a + ma') dt,$$

whence on integration

$$\log \left( x + my + \frac{c + mc'}{a + ma'} \right) = (a + ma') t + C \dots\dots(c).$$

In this equation it only remains to substitute in succession the two values of  $m$  furnished by (b). The two resulting equations, in which the arbitrary constants must of course be supposed different, will express the complete solution of the problem.

When the values of  $m$  are equal, the form (c) furnishes directly only a single equation of the complete solution. We may deduce the other equation, either by the method of limits (assuming the law of continuity), or by eliminating  $x$  from the given system by means of (c), and then forming a new differential equation between  $y$  and  $t$ . It seems preferable however to employ the general method of Art. 5, by which all difficulties connected with the presence of equal or imaginary roots are referred to the corresponding cases of ordinary differential equations.

7. Simultaneous equations are so often presented under the symmetrical form (11) that the appropriate mode of treatment deserves to be carefully studied, especially as it possesses the superiority, always in point of elegance, and frequently in point of convenience, over other processes.

It is known that each member of a system of equal fractions is equal to the fraction which would be formed by

dividing any linear homogeneous function of their numerators by the same function of their denominators. Hence if we have a system of equations of the form

$$\frac{dx_1}{X_1} = \frac{dx_2}{X_2} \dots\dots = \frac{dx_n}{X_n} = \frac{dt}{T} \dots\dots\dots (16),$$

in which we suppose  $t$  the independent variable, and  $T$  a function of  $t$  only, then we shall have

$$\frac{dt}{T} = \frac{dx_1 + m dx_2 \dots + r dx_n}{X_1 + m X_2 \dots + r X_n} \dots\dots\dots (17).$$

Hence, should the first member be an exact differential, the inquiry is suggested whether the multipliers  $m, \dots r$  cannot be so determined, whether as functions of the variables or as constants, as to render the second member such also. Now when the system of equations is linear and with constant coefficients this can always be effected. It may be observed that the *character* of the system is as manifest from inspection of the symmetrical form (16) as of the ordinary form. If the system be linear and with constant coefficients the denominators  $X_1, X_2, \dots X_n$  will, when considered with respect to the dependent variables  $x_1, x_2, \dots x_n$ , be linear and with constant coefficients.

In the employment of this method it is often of great advantage to introduce a new independent variable, and to consider all the variables of the given system as dependent upon it. We are thus enabled to secure the condition above adverted to, of having one member of the symmetrical system an exact differential.

Ex. 1. Given  $\frac{dx}{ax + by + c} = \frac{dy}{a'x + b'y + c'}$ ,

Let us introduce a new variable  $t$  so as to give to the system the form

$$\frac{dx}{ax + by + c} = \frac{dy}{a'x + b'y + c'} = \frac{dt}{t} \dots\dots\dots (a).$$

Here the third member being an exact differential, we shall write

$$\begin{aligned}\frac{dt}{t} &= \frac{dx + mdy}{ax + by + c + m(a'x + b'y + c')} \\ &= \frac{dx + mdy}{(a + ma')x + (b + mb')y + c + mc'} \\ &= \frac{1}{a + ma'} \frac{(a + ma')dx + (a + ma')mdy}{(a + ma')x + (b + mb')y + c + mc'}.\end{aligned}$$

The second member of this equation will be an exact differential if we have

$$(a + ma')m = b + mb' \dots\dots\dots (b),$$

the integral corresponding to each value of  $m$  thus determined being of the form

$$\log t + C = \frac{1}{a + ma'} \log \{(a + ma')x + (b + mb')y + c + mc'\},$$

$$\text{or} \quad C' t = \{ax + by + c + m(a'x + b'y + c')\}^{\frac{1}{a + ma'}}$$

If the roots of the quadratic (b) are  $m_1$  and  $m_2$ , we thus find

$$\left. \begin{aligned}C_1 t &= \{ax + by + c + m_1(a'x + b'y + c')\}^{\frac{1}{a + m_1 a'}} \\ C_2 t &= \{ax + by + c + m_2(a'x + b'y + c')\}^{\frac{1}{a + m_2 a'}}\end{aligned} \right\} \dots\dots (c),$$

for the primitive equations of the system (a). Those of the given system will be obtained by eliminating  $t$ . The result assumes the remarkable form

$$\frac{\{ax + by + c + m_1(a'x + b'y + c')\}^{\frac{1}{a + m_1 a'}}}{\{ax + by + c + m_2(a'x + b'y + c')\}^{\frac{1}{a + m_2 a'}}} = C \dots\dots (d).$$

Ex. 2. Given  $\frac{dx}{X} = \frac{dy}{Y} = \frac{dz}{Z}$ , where

$$\left. \begin{aligned}X &= ax + by + cz + d \\ Y &= a'x + b'y + c'z + d' \\ Z &= a''x + b''y + c''z + d''\end{aligned} \right\} \dots\dots\dots (a).$$

Introducing a new variable  $t$ , so as to give to the system the more complete form

$$\frac{dt}{t} = \frac{dx}{X} = \frac{dy}{Y} = \frac{dz}{Z} \dots\dots\dots (b),$$

we have

$$\begin{aligned} \frac{dt}{t} &= \frac{l dx + m dy + n dz}{l X + m Y + n Z} \\ &= \frac{l dx + m dy + n dz}{\lambda (lx + my + nz + r)} \dots\dots\dots (c). \end{aligned}$$

Provided that we assume

$$\left. \begin{aligned} al + a'm + a''n &= \lambda l \\ bl + b'm + b''n &= \lambda m \\ cl + c'm + c''n &= \lambda n \\ dl + d'm + d''n &= \lambda r \end{aligned} \right\} \dots\dots\dots (d).$$

The first three of these may be written in the form

$$\left. \begin{aligned} (a - \lambda) l + a'm + a''n &= 0 \\ bl + (b' - \lambda) m + b''n &= 0 \\ cl + c'm + (c'' - \lambda) n &= 0 \end{aligned} \right\} \dots\dots\dots (e),$$

whence eliminating  $l, m, n$  we have the well-known cubic

$$\begin{aligned} (a - \lambda) (b' - \lambda) (c'' - \lambda) - b''c' (a - \lambda) \\ - ca'' (b' - \lambda) - ba' (c'' - \lambda) + a'b''c + a''bc' = 0 \dots (f). \end{aligned}$$

Now let the values of  $\lambda$  hence found be  $\lambda_1, \lambda_2, \lambda_3$ , and the corresponding values of  $l, m, n, r$  be  $l_1, m_1, n_1, r_1, l_2, m_2, \&c.$ , then integrating (c) we shall have the system

$$\begin{aligned} c_1 t &= (l_1 x + m_1 y + n_1 z + r_1)^{\frac{1}{\lambda_1}}, \\ c_2 t &= (l_2 x + m_2 y + n_2 z + r_2)^{\frac{1}{\lambda_2}}, \\ c_3 t &= (l_3 x + m_3 y + n_3 z + r_3)^{\frac{1}{\lambda_3}}. \end{aligned}$$

Hence eliminating  $t$  by equating its values, we find as the general solution of the original system of equations

$$\begin{aligned}
 (l_1x + m_1y + n_1z + r_1)^{\frac{1}{\lambda_1}} &= C (l_2x + m_2y + n_2z + r_2)^{\frac{1}{\lambda_2}} \\
 &= C' (l_3x + m_3y + n_3z + r_3)^{\frac{1}{\lambda_3}} \dots (g).
 \end{aligned}$$

In the same way we may integrate the general system

$$\frac{dx_1}{X_1} = \frac{dx_2}{X_2} \dots = \frac{dx_n}{X_n},$$

where  $X_1, X_2, \dots, X_n$  are any linear functions of the variables.

8. From the above results the solutions of various symmetrical systems in which the denominators are not linear may be deduced. The most remarkable of such deductions is the following.

Suppose that in the system

$$\frac{dx'}{ax' + by' + cz'} = \frac{dy'}{a'x' + b'y' + c'z'} = \frac{dz'}{a''x' + b''y' + c''z'} \dots (a),$$

the solution of which is known from what precedes, we substitute

$$x' = xz', \quad y' = yz',$$

$x$  and  $y$  being new variables introduced in the place of  $x'$  and  $y'$ . The result is

$$\frac{z'dx + xdz'}{ax + by + c} = \frac{z'dy + ydz'}{a'x + b'y + c'} = \frac{dz'}{a''x + b''y + c''},$$

to which we may obviously give the form

$$\begin{aligned}
 \frac{z'dx}{ax + by + c - x(a''x + b''y + c'')} &= \frac{z'dy}{a'x + b'y + c' - y(a''x + b''y + c'')} \\
 &= \frac{dz'}{a''x + b''y + c''}.
 \end{aligned}$$

Dividing the first equation of this system by  $z'$ , we have

$$\frac{dx}{ax + by + c - x(a''x + b''y + c'')} = \frac{dy}{a'x + b'y + c' - y(a''x + b''y + c'')} \dots (b).$$

Now this on clearing of fractions will be found to be of the same form as Jacobi's equation (*Crelle*, Tom. XXIV. p. 1), whose solution on other grounds has been explained, Chap. v. Art. 8.

We see that the solution of (b) is deducible from that of the system (a) by changing  $x'$  into  $xz'$ ,  $y'$  into  $yz'$ , and eliminating  $z'$ .

And just in this way the solution of any symmetrical non-linear system of the form

$$\frac{dx_1}{X_1 - x_1 X} = \frac{dx_2}{X_2 - x_2 X} \cdots = \frac{dx_n}{X_n - x_n X} \cdots \cdots (18),$$

in which  $X, X_1, X_2, \dots, X_n$  are linear functions of the variables  $x_1, x_2, \dots, x_n$  may be made to flow from that of a symmetrical system of the form

$$\frac{dx_1}{X_1} = \frac{dx_2}{X_2} \cdots = \frac{dx_{n+1}}{X_{n+1}} \cdots \cdots (19),$$

in which  $X_1, X_2, \dots, X_{n+1}$  are linear *homogeneous* functions of the variables  $x_1, x_2, \dots, x_{n+1}$ . The general solution of the system (18) seems to have been first obtained by Hesse (*Crelle*, Tom. xxv. p. 171).

9. Lastly, certain systems of linear equations which have not constant coefficients may be solved by the above method.

Thus the solution of the equations

$$\left. \begin{aligned} \frac{dx}{dt} + T(ax + by) &= T_1 \\ \frac{dy}{dt} + T(a'x + b'y) &= T_2 \end{aligned} \right\} \cdots \cdots \cdots (a),$$

where  $T, T_1, T_2$  are functions of the independent variable, may be reduced to that of an ordinary linear differential equation of the first order.

For proceeding as before, we find

$$\frac{d(x + my)}{dt} + \lambda T(x + my) = T_1 + mT_2 \cdots \cdots (b),$$

provided that  $\lambda$  and  $m$  be determined by the conditions

$$\lambda = a + ma', \quad \lambda m = b + mb' \cdots \cdots (c).$$

Hence eliminating  $\lambda$ , we have

$$m(a + ma') = b + mb' \dots\dots\dots (d),$$

which gives two values for  $m$ . Integrating (b) regarded as a linear equation of the first order between  $x + my$  and  $t$ , and substituting for  $\lambda$  its value in terms of  $m$  given by the first equation of the system (c), we have

$$x + my = e^{-(a+ma')\int T dt} \left\{ C + \int e^{(a+ma')\int T dt} (T_1 + mT_2) dt \right\} \dots (e),$$

in which it remains to substitute for  $m$  its values given by (d).

Ex. Given  $\frac{dx}{dt} + \frac{2}{t}(x - y) = 1$ ,  $\frac{dy}{dt} + \frac{1}{t}(x + 5y) = t$ .

The solution is

$$x + y = \frac{1}{t^3} \left( C_1 + \frac{t^4}{4} + \frac{t^5}{5} \right), \quad x + 2y = \frac{1}{t^4} \left( C_2 + \frac{t^5}{5} + \frac{t^6}{3} \right).$$

If in the system (a) we make  $T = 1$ , it becomes a system of equations with constant coefficients but possessed of second members.

The general system analogous to (a) when the number of variables is increased, may be solved by the same method. It may be well to notice that the equivalent symmetrical form is

$$\frac{dx_1}{X_1 + T_1} = \frac{dx_2}{X_2 + T_2} \dots = \frac{dx_n}{X_n + T_n} = \frac{dt}{T} \dots\dots\dots (20),$$

where  $X_1, X_2, \dots, X_n$  are linear homogeneous functions of the dependent variables, and  $T, T_1, \dots, T_n$  are functions of  $t$ . Treated under this form, it is obvious that its solution will be made to depend upon that of a linear differential equation of the first order, and an auxiliary algebraic equation of the  $n^{\text{th}}$  degree.

*Equations of an order higher than the first.*

10. Any system of simultaneous equations of an order higher than the first is reducible to a system of the first

order. And this reduction though not always necessary for the purpose of solution is theoretically important, because it enables us to predicate what *kind* of solution is possible.

To effect this reduction it is only necessary to regard as a new variable and to express as such by a new symbol, each differential coefficient, except the highest, of each dependent variable in the given equations. The transformed equations will thus be of the first order, and the connecting relations of the first order also; and the two together will constitute a system of simultaneous equations of the first order.

Ex. Given the dynamical system

$$\frac{d^2x}{dt^2} = X, \quad \frac{d^2y}{dt^2} = Y, \quad \frac{d^2z}{dt^2} = Z,$$

where  $X, Y, Z$  are functions of the variables.

Here if we assume

$$\frac{dx}{dt} = x', \quad \frac{dy}{dt} = y', \quad \frac{dz}{dt} = z',$$

the given system assumes the form

$$\frac{dx'}{dt} = X, \quad \frac{dy'}{dt} = Y, \quad \frac{dz'}{dt} = Z.$$

Thus we have in the whole six equations of the first order between the six dependent variables  $x, y, z, x', y', z'$ , and the independent variable  $t$ .

The complete solution of the latter system will therefore consist of six equations connecting the above system of variables with six arbitrary constants.

If from these six equations we eliminate the three new variables  $x', y', z'$ , we obtain three equations connecting the original variables  $x, y, z, t$  with the above-mentioned six arbitrary constants.

And thus it might be shewn that the complete solution of any system of three differential equations of the second order between four variables will be expressed by three primitive equations connecting these variables with six arbitrary constants.

*And still more generally, the complete solution of a system of  $n$  differential equations containing  $n + 1$  variables of which one is independent will consist of  $n$  equations connecting those variables with a number of constants equal to the sum of the indices of order of the several highest differential coefficients.*

For let  $t$  be the independent and  $x$  one of the dependent variables, and let the highest differential coefficient of  $x$  which presents itself be  $\frac{d^n x}{dt^n}$ . Then in the reduction of the system of given equations to a system of equations of the first order it is necessary to introduce  $n - 1$  new variables connected with  $x$  by the relations

$$\frac{dx}{dt} = x_1, \quad \frac{dx_1}{dt} = x_2, \dots \frac{dx_{n-2}}{dt} = x_{n-1}.$$

Thus the number of variables in the transformed system corresponding to  $x$  and its differential coefficients will be  $n$ , and as a similar remark applies to all the other variables, it appears that the total number of variables of the transformed system will be equal to the sum of the indices of the orders of the highest differential coefficients of the several dependent variables in the system given. Such then will be the number of equations of the transformed system, and such the number of constants introduced by their complete integration. Art. 5.

It is also evident that if from the equations by which the complete solution is expressed we eliminate all the new variables there will remain a number of equations equal in number to the original equations, and connecting the primitive variables with the constants above mentioned. Thus the proposition is established.

The transformation above employed is further important, because in the highest class of researches on theoretical dynamics it is always supposed that the differential equations of motion are reduced to a system of simultaneous equations of the first order.

At the same time it is not necessary for ordinary purposes to effect this reduction. Differentiation and elimination always enable us to arrive at a differential equation, higher in order, between two of the variables. The method of indeter-

minate multipliers may also be sometimes used with advantage. No *general* rule can however be given.

[The statement respecting the number of arbitrary constants is not universally true. Suppose, for example, that there are two simultaneous differential equations which connect  $x$  and  $y$  with the independent variable  $t$ . Let one equation contain differential coefficients up to  $\frac{d^m x}{dt^m}$  and  $\frac{d^n y}{dt^n}$  inclusive; and let the other equation contain differential coefficients up to  $\frac{d^r x}{dt^r}$  and  $\frac{d^s y}{dt^s}$  inclusive: then it can be shewn that the number of arbitrary constants involved in the solution is the greater of the two numbers  $m + s$  and  $n + r$ . See Cournot, *Traité Élémentaire de la Théorie des Fonctions*...1841. Vol. II. p. 318.]

Ex. 1. Given  $\frac{d^2 x}{dt^2} = ax + by$ ,  $\frac{d^2 y}{dt^2} = a'x + b'y$ .

1st method. Differentiating the first equation twice with respect to  $t$ , we have

$$\frac{d^4 x}{dt^4} = a \frac{d^2 x}{dt^2} + b \frac{d^2 y}{dt^2}.$$

Eliminating  $y$  and  $\frac{d^2 y}{dt^2}$  from the above three equations, we have

$$\frac{d^4 x}{dt^4} - (a + b') \frac{d^2 x}{dt^2} + (ab' - a'b) x = 0 \dots\dots\dots(a).$$

The complete integral of this linear equation with constant coefficients will determine  $x$ , whence  $y$  is given by the formula

$$y = \frac{1}{b} \left( \frac{d^2 x}{dt^2} - ax \right).$$

2nd method. From the given equations we find

$$\begin{aligned} \frac{d^2 x}{dt^2} + m \frac{d^2 y}{dt^2} &= (a + ma') x + (b + mb') y \\ &= (a + ma') \left( x + \frac{b + mb'}{a + ma'} y \right). \end{aligned}$$

Let  $x + my = u$ , then provided that we determine  $m$  by the condition

$$m = \frac{b + mb'}{a + ma'} \dots\dots\dots (b),$$

we shall have

$$\frac{d^2u}{dt^2} = (a + ma') u,$$

whence 
$$u = C_1 \epsilon^{(a+ma')\frac{1}{2}t} + C_2 \epsilon^{-(a+ma')\frac{1}{2}t}.$$

Let  $m_1, m_2$  be the values of  $m$  given by (b), then the complete primitive system is

$$x + m_1 y = C_1 \epsilon^{(a+m_1 a')\frac{1}{2}t} + C_2 \epsilon^{-(a+m_1 a')\frac{1}{2}t},$$

$$x + m_2 y = C_3 \epsilon^{(a+m_2 a')\frac{1}{2}t} + C_4 \epsilon^{-(a+m_2 a')\frac{1}{2}t},$$

and this is really equivalent to the previous solution, though more symmetrical.

Ex. 2. The approximate equations for the horizontal motion of a pendulum when the influence of the earth's rotation is taken into account\* are

$$\left. \begin{aligned} \frac{d^2x}{dt^2} - 2r \frac{dy}{dt} + \frac{gx}{l} &= 0 \\ \frac{d^2y}{dt^2} + 2r \frac{dx}{dt} + \frac{gy}{l} &= 0 \end{aligned} \right\} \dots\dots\dots (a),$$

$l$  representing the length of the pendulum,  $g$  the force of gravity, and  $-r$  being equal to the product of the earth's angular velocity into the sine of the latitude of the place.

As the equations have constant coefficients they admit of complete integration. If we differentiate so as to enable us to eliminate  $y, \frac{dy}{dt}$  and  $\frac{d^2y}{dt^2}$ , we find as the result

$$\frac{d^4x}{dt^4} + 2 \left( 2r^2 + \frac{g}{l} \right) \frac{d^2x}{dt^2} + \frac{g^2}{l^2} x = 0 \dots\dots\dots (b),$$

\* Jullien, *Problèmes de Mécanique Rationnelle*, Tom. II. p. 233.

the complete solution of which is of the form

$$x = A \cos (m_1 t + \alpha) + B \cos (m_2 t + \beta) \dots\dots\dots (c),$$

where  $A$ ,  $\alpha$ ,  $B$ ,  $\beta$  are arbitrary constants, and  $m_1^2$ ,  $m_2^2$  are the two roots, with signs changed, of the equation

$$\mu^2 - 2 \left( 2r^2 + \frac{g}{l} \right) \mu + \frac{g^2}{l^2} = 0.$$

From the above value of  $x$  that of  $y$  may be obtained by means of the formula

$$y = -\frac{l}{2rg} \frac{d^3 x}{dt^3} - \frac{l}{g} \left( 2r + \frac{g}{2rl} \right) \frac{dx}{dt} \dots\dots\dots (d),$$

which is readily deduced from the given equations.

The above system may also be solved by assuming

$$\left. \begin{aligned} x &= x' \cos rt + y' \sin rt \\ y &= -x' \sin rt + y' \cos rt \end{aligned} \right\} \dots\dots\dots (e).$$

The transformed equations are

$$\frac{d^2 x'}{dt^2} + \lambda^2 x' = 0, \quad \frac{d^2 y'}{dt^2} + \lambda^2 y' = 0,$$

where

$$\lambda^2 = r^2 + \frac{g}{l};$$

whence we find

$$\left. \begin{aligned} x' &= A \cos \lambda t + B \sin \lambda t \\ y' &= A' \cos \lambda t + B' \sin \lambda t \end{aligned} \right\} \dots\dots\dots (f).$$

11. In problems connected with central forces particular forms of the following system of equations present themselves, viz.

$$\frac{d^2 x}{dt^2} = \frac{dR}{dx}, \quad \frac{d^2 y}{dt^2} = \frac{dR}{dy}, \quad \frac{d^2 z}{dt^2} = \frac{dR}{dz} \dots\dots\dots (a),$$

where  $R$  is a given function of the quantity  $\sqrt{(x^2 + y^2 + z^2)}$

or  $r$ . Multiplying the above equations by  $dx$ ,  $dy$ ,  $dz$  respectively, and integrating, we have

$$\frac{1}{2} \left\{ \left( \frac{dx}{dt} \right)^2 + \left( \frac{dy}{dt} \right)^2 + \left( \frac{dz}{dt} \right)^2 \right\} = R + B \dots\dots\dots (b),$$

$B$  being an arbitrary constant.

Again, since  $\frac{dR}{dx} = \frac{dR}{dr} \frac{dr}{dx} = \frac{x}{r} \frac{dR}{dr}$ , &c. the given system of equations may be expressed in the form

$$\frac{d^2x}{dt^2} = \frac{x}{r} \frac{dR}{dr}, \quad \frac{d^2y}{dt^2} = \frac{y}{r} \frac{dR}{dr}, \quad \frac{d^2z}{dt^2} = \frac{z}{r} \frac{dR}{dr}.$$

Now if from each pair of equations we eliminate  $\frac{dR}{dr}$ , we obtain

$$x \frac{d^2y}{dt^2} - y \frac{d^2x}{dt^2} = 0, \quad y \frac{d^2z}{dt^2} - z \frac{d^2y}{dt^2} = 0, \quad z \frac{d^2x}{dt^2} - x \frac{d^2z}{dt^2} = 0,$$

of which it is evident that two only are independent. Integrating these, we have

$$x \frac{dy}{dt} - y \frac{dx}{dt} = C_1, \quad y \frac{dz}{dt} - z \frac{dy}{dt} = C_2, \quad z \frac{dx}{dt} - x \frac{dz}{dt} = C_3,$$

$C_1, C_2, C_3$  being constants.

Squaring the last three equations and adding, we obtain a result which may be expressed in the form

$$(x^2 + y^2 + z^2) \left\{ \left( \frac{dx}{dt} \right)^2 + \left( \frac{dy}{dt} \right)^2 + \left( \frac{dz}{dt} \right)^2 \right\} - \left( x \frac{dx}{dt} + y \frac{dy}{dt} + z \frac{dz}{dt} \right)^2 = C_1^2 + C_2^2 + C_3^2 = A^2,$$

or, by virtue of (b) and of the known value of  $r$ ,

$$2r^2 (R + B) - \left( r \frac{dr}{dt} \right)^2 = A^2 \dots\dots\dots (c),$$

whence

$$dt = \frac{r dr}{\sqrt{2r^2 (R + B) - A^2}} \dots\dots\dots (d),$$

$$t + \alpha = \int \frac{r dr}{\sqrt{2r^2 (R + B) - A^2}} \dots\dots\dots (e).$$

Again, it is evident that by means of (c) we can eliminate  $R$  from each equation of the system (a). For (c) gives

$$R = -B + \frac{1}{2} \left\{ \frac{A^2}{r^2} + \left( \frac{dr}{dt} \right)^2 \right\}.$$

Substituting which in the first of the given equations, we have

$$\begin{aligned} \frac{d^2x}{dt^2} &= \frac{x}{r} \left( -\frac{A^2}{r^3} + \frac{dr}{dt} \frac{d}{dr} \frac{dr}{dt} \right) \\ &= \frac{x}{r} \left( -\frac{A^2}{r^3} + \frac{d^2r}{dt^2} \right). \end{aligned}$$

Hence

$$r \frac{d^2x}{dt^2} - x \frac{d^2r}{dt^2} + \frac{A^2x}{r^3} = 0,$$

or

$$\frac{d}{dt} r^2 \frac{d}{dt} \frac{x}{r} + \frac{A^2x}{r^3} = 0;$$

therefore

$$r^2 \frac{d}{dt} r^2 \frac{d}{dt} \left( \frac{x}{r} \right) + A^2 \frac{x}{r} = 0.$$

If we now assume  $\frac{A dt}{r^2} = d\phi$ , the above becomes

$$\frac{d^2 \left( \frac{x}{r} \right)}{d\phi^2} + \frac{x}{r} = 0,$$

whence

$$\frac{x}{r} = a_1 \cos \phi + b_1 \sin \phi \dots\dots\dots (f).$$

In like manner, we find

$$\frac{y}{r} = a_2 \cos \phi + b_2 \sin \phi \dots\dots\dots (g),$$

$$\frac{z}{r} = a_3 \cos \phi + b_3 \sin \phi \dots\dots\dots (h),$$

in which we must substitute for  $\phi$  its value, viz.

$$\phi = \int \frac{A dt}{r^2} = \int \frac{A dr}{r \sqrt{\{2r^2 (R + B) - A^2\}}} \dots\dots\dots (i).$$

To this expression it would be superfluous to annex an arbitrary constant before that substitution. For each of the second members of  $(f)$ ,  $(g)$ ,  $(h)$  is expressible in the form  $C \cos(\phi + U')$ , in which  $\phi$  is already provided with an arbitrary constant.

The solution is therefore expressed by means of  $(e)$  and  $(i)$ , which determine  $r$  and the auxiliary  $\phi$  as functions of  $t$ , and by  $(f)$ ,  $(g)$ ,  $(h)$ , which then enable us to express  $x$ ,  $y$ ,  $z$  as functions of  $t$ . As we have however made no attempt to preserve independence in the series of results, the constants will not be independent. If we add the squares of  $(f)$ ,  $(g)$ ,  $(h)$ , we shall have

$$1 = (a_1^2 + a_2^2 + a_3^2) \cos^2 \phi + 2(a_1 b_1 + a_2 b_2 + a_3 b_3) \sin \phi \cos \phi + (b_1^2 + b_2^2 + b_3^2) \sin^2 \phi,$$

which involves the relations among the constants

$$a_1^2 + a_2^2 + a_3^2 = 1, \quad b_1^2 + b_2^2 + b_3^2 = 1, \quad a_1 b_1 + a_2 b_2 + a_3 b_3 = 0 \dots (k).$$

The six constants in  $(f)$ ,  $(g)$ ,  $(h)$ , thus limited, supply the place of only three arbitrary constants, and there being three also involved in  $(e)$ , the total number is six, as it ought to be.

In the same way we may integrate the more general system

$$\frac{d^2 x_1}{dt^2} = \frac{dR}{dx_1}, \quad \frac{d^2 x_2}{dt^2} = \frac{dR}{dx_2}, \dots \quad \frac{d^2 x_n}{dt^2} = \frac{dR}{dx_n},$$

where  $R$  is a function of  $\sqrt{(x_1^2 + x_2^2 \dots + x_n^2)}$ . The results, which have no application in our astronomy, are of the form which the above analysis would suggest. Binet, to whom the method is due, has applied it to the problem of elliptic motion. (Liouville, Tom. II. p. 457.) For all practical ends the employment of polar co-ordinates, as explained in treatises on dynamics, is to be preferred.

12. The following example presents itself in a discussion by M. Liouville\*, of a very interesting case of the problem of three bodies.

\* *Sur un cas particulier du Problème des trois corps. Journal de Mathématiques*, Tom. I. 2nd series, p. 248.

Ex. Given

$$\frac{d^2u}{dt^2} + n^2 \{u - 3x' (ux' + vy')\} = 0,$$

$$\frac{d^2v}{dt^2} + n^2 \{v - 3y' (ux' + vy')\} = 0;$$

where, for brevity,  $x'$  is put for  $\cos (at + b)$ ,  $y'$  for  $\sin (at + b)$ .

If we transform the above equation by assuming

$$ux' + vy' = U, \quad uy' - vx' = V,$$

we find, after all reductions are effected,

$$\frac{d^2U}{dt^2} + 2a \frac{dV}{dt} - (a^2 + 2n^2) U = 0,$$

$$\frac{d^2V}{dt^2} - 2a \frac{dU}{dt} + (n^2 - a^2) V = 0.$$

And these equations being linear and with constant coefficients, may be integrated by the process of the previous section.

### EXERCISES.

1.  $\frac{dx}{dt} + 4x + \frac{y}{4} = 0, \quad \frac{dy}{dt} + 3y - x = 0.$
2.  $\frac{dx}{dt} + 7x - y = 0, \quad \frac{dy}{dt} + 2x + 5y = 0.$
3.  $4 \frac{dx}{dt} + 9 \frac{dy}{dt} + 44x + 49y = t, \quad 3 \frac{dx}{dt} + 7 \frac{dy}{dt} + 34x + 38y = e^t.$
4.  $\frac{dx}{dt} + 5x + y = e^t, \quad \frac{dy}{dt} + 3y - x = e^{2t}.$
5.  $\frac{dx}{2y - 5x + e^t} = \frac{dy}{x - 6y + e^{2t}} = dt.$

$$6. \quad -dx = \frac{dy}{3y+4z} = \frac{dz}{2y+5z}.$$

$$7. \quad \frac{d^2x}{dt^2} - 3x - 4y + 3 = 0, \quad \frac{d^2y}{dt^2} + x - 8y + 5 = 0.$$

$$8. \quad \frac{d^2x}{dt^2} - 3x - 4y + 3 = 0, \quad \frac{d^2y}{dt^2} + x + y + 5 = 0.$$

$$9. \quad \frac{d^2x}{dt^2} + m^2x = 0, \quad \frac{d^2y}{dt^2} - m^2x = 0.$$

$$10. \quad \text{Given } \frac{dx}{X+T_1} = \frac{dy}{Y+T_2} = \frac{dz}{Z+T_3} = \frac{dt}{T}, \text{ where}$$

$$X = ax + by + cz,$$

$$Y = a'x + b'y + c'z,$$

$$Z = a''x + b''y + c''z,$$

and  $T, T_1, T_2, T_3$  are functions of  $t$ .

11. What is the general form of the solution of a system of  $n$  simultaneous equations of the first order between  $n+1$  variables?

12. What number of constants will be involved in the solution of a system of three simultaneous equations of the first, second and fourth order respectively between four variables?

13. Of the system of dynamical equations,

$$\frac{d^2x}{dt^2} + \frac{\mu x}{r^3} = 0, \quad \frac{d^2y}{dt^2} + \frac{\mu y}{r^3} = 0, \quad \frac{d^2z}{dt^2} + \frac{\mu z}{r^3} = 0,$$

where  $r = (x^2 + y^2 + z^2)^{\frac{1}{2}}$ , seven first integrals are obtained of which it is subsequently found that five only are independent. How many final integrals can hence be deduced without proceeding to another integration?

14. Given  $a \frac{dx}{dt} = (b - c) yz \dots \dots \dots (1),$

$b \frac{dy}{dt} = (c - a) zx \dots \dots (2), \quad c \frac{dz}{dt} = (a - b) xy \dots \dots \dots (3).$

Putting  $\frac{a}{b-c}=l, \quad \frac{b}{c-a}=m, \quad \frac{c}{a-b}=n$  we find, on eliminating  $dt,$

$$lxdx = mydy = nzdz,$$

from which  $y$  and  $z$  will be found in terms of  $x$ , and their values will reduce (1) to a differential equation of the first order between  $x$  and  $t$ .

Or multiply the given equations, first by  $x, y, z$ , respectively, add the results and integrate; 2ndly by  $ax, by, cz$ , respectively, add the results and integrate. Then by means of the integrals obtained eliminate two of the variables from any of the given equations.

15. Shew that in the example of Art. 12, the transformation

$$x = x' \cos (rt + \epsilon) + y' \sin (rt + \epsilon),$$

$$y = -x' \sin (rt + \epsilon) + y' \cos (rt + \epsilon),$$

$\epsilon$  being an arbitrary constant, would not lead to a more general solution than the one actually arrived at.

## CHAPTER XIV.

### OF PARTIAL DIFFERENTIAL EQUATIONS.

1. PARTIAL differential equations are distinguished by the fact that they involve partial differential coefficients in their expression, and therefore indicate the existence of more than one independent variable. Chap. I. Art. 2.

The nature of these equations will be best explained by one or two examples of the mode of their formation.

Ex. 1. The general equation of cylindrical surfaces is

$$x - lz = \phi(y - mz) \dots \dots \dots (1),$$

$\phi$  being a functional symbol, and  $l$  and  $m$  constants determining the direction of the generating line. As this is a relation connecting three variables we are permitted to regard two of them as independent. Choosing  $x$  and  $y$  as the independent variables, and differentiating with respect to them in succession,  $z$  being regarded as dependent on them both, we have

$$1 - l \frac{dz}{dx} = -m \phi'(y - mz) \frac{dz}{dx} \dots \dots \dots (2),$$

$$-l \frac{dz}{dy} = \phi'(y - mz) \left(1 - m \frac{dz}{dy}\right) \dots \dots \dots (3).$$

Eliminating the function  $\phi'(y - mz)$ , there results

$$l \frac{dz}{dx} + m \frac{dz}{dy} = 1 \dots \dots \dots (4),$$

the partial differential equation of cylindrical surfaces. Of this equation (1) is termed the general primitive.

In the above example a linear partial differential equation of the first order has been formed by the elimination of a single arbitrary function.

Ex. 2. If we assume as a primitive equation

$$z = ax + by - ab \dots\dots\dots(5),$$

and, regarding  $x$  and  $y$  as independent, differentiate with respect to these variables in succession, we have

$$\frac{dz}{dx} = a, \quad \frac{dz}{dy} = b.$$

Eliminating  $a$  and  $b$  by substitution in the primitive, there results

$$z = x \frac{dz}{dx} + y \frac{dz}{dy} - \frac{dz}{dx} \frac{dz}{dy} \dots\dots\dots(6),$$

a partial differential equation of the first order, *but not* linear.

Now this equation has been formed by the elimination not of an arbitrary function but of two arbitrary constants. The equation (5) is here, by way of distinction, called the *complete* primitive. The epithets *general* and *complete* have been employed by Lagrange to denote the two kinds of generality which arise from arbitrary functions, and from arbitrary constants, respectively.

Ex. 3. Given  $z = \phi(y + ax) + \psi(y - ax)$ , where  $\phi$  and  $\psi$  are arbitrary symbols of functionality.

Proceeding to differential coefficients of the second order we find

$$\frac{d^2z}{dx^2} = a^2 \{ \phi''(y + ax) + \psi''(y - ax) \},$$

$$\frac{d^2z}{dy^2} = \phi''(y + ax) + \psi''(y - ax),$$

whence

$$\frac{d^2z}{dx^2} = a^2 \frac{d^2z}{dy^2} \dots\dots\dots(7),$$

a partial differential equation of the second order and of the first degree.

And this equation has been formed by the elimination of two arbitrary functions from the *general* primitive.

These examples illustrate the usual, and what may perhaps with propriety be termed the *primary*, modes of genesis of partial differential equations, viz. the elimination of arbitrary functions, and the elimination of arbitrary constants. It is to be noted that these modes are perfectly distinct. Thus we might in Ex. 1, by specifying the form of the function  $\phi$ , eliminate the constants  $l$  and  $m$  from the primitive (1), and the derived equations (2) and (3), instead of eliminating the functional forms from the two latter; but the result would differ in character, as well as in the mode of its origin, from that which has been actually obtained. We must bear in mind that when from a primitive equation of given form different partial differential equations are derived, it is owing to a difference of assumption as to what is to be regarded as arbitrary; so that we are not permitted to say that to the *same* primitive, considered in the same sense of generality, different partial differential equations belong.

In Ex. 1, a partial differential equation of the first order has been formed from a general primitive containing one arbitrary function, and in Ex. 3 a partial differential equation of the second order has been formed from a general primitive containing two arbitrary functions. These examples exhibit a certain analogy with the genesis of ordinary differential equations, the order of the equation being equal to the number of constants in its primitive. But this analogy is not general. For let

$$F\{x, y, z, \phi(u), \psi(v)\} = 0,$$

be an assumed primitive containing two arbitrary functions  $\phi(u)$ ,  $\psi(v)$ , where  $u$  and  $v$  are given functions of  $x, y, z$ . Then representing the first member by  $F$ , regarding  $x$  and  $y$  as independent variables, and forming all possible derived equations up to the second order, we have

$$\begin{aligned} \frac{dF}{dx} = 0, \quad \frac{dF}{dy} = 0, \\ \frac{d^2F}{dx^2} = 0, \quad \frac{d^2F}{dx dy} = 0, \quad \frac{d^2F}{dy^2} = 0, \end{aligned}$$

which with the given equation make six equations. But these containing the six functions

$$\phi(u), \psi(v), \phi'(u), \psi'(v), \phi''(u), \psi''(v),$$

do not, in general, suffice to enable us by the elimination of the latter, to form a partial differential equation of the second order free from arbitrary functions.

We see then, 1st, that partial differential equations do not arise from the elimination of arbitrary functions only; 2ndly, that even as respects this mode of genesis, no general canons exist similar to those which govern the connexion of ordinary differential equations with their primitives. On both these grounds it will be proper, in considering special classes of equations, to examine their special origin and to seek therein the clue to their solution.

*Solution of partial differential equations.*

2. Before proceeding to general theories of the solution of partial differential equations, it may be noticed that there are some equations of which the solution may be directly reduced to that of ordinary differential equations.

This is the case when the partial differential coefficients have all been formed with respect to one only of the variables. We can then integrate as if this were in fact the only independent variable, provided that we finally introduce arbitrary functions of the other independent variables in the place of arbitrary constants.

Ex. 1. Given  $x + y \frac{dz}{dx} = 0$ .

Multiplying by  $dx$ , integrating with respect to  $x$ , and adding an arbitrary function of  $y$ , we have

$$\frac{x^2}{2} + yz = \phi(y),$$

the solution required.

It is *permitted* in the above, and in all similar cases, to complete the solution by adding an arbitrary function of  $y$ , because, with reference to the integration effected,  $y$  is constant; and it is *necessary* to add such a complementary function in order to obtain the most general solution, because an arbitrary function of one of the variables is more general than an arbitrary constant not involving that variable.

Ex. 2. Given  $y \frac{dz}{dy} - 2x - 2z - y = 0$ .

This equation may be expressed in the form

$$\frac{dz}{dy} - \frac{2}{y} z = 1 + \frac{2x}{y}.$$

Involving no differential coefficient with respect to  $x$ , it may be treated as a linear differential equation of the first order in which  $y$  is the independent, and  $z$  the dependent variable; only instead of an arbitrary constant we must add an arbitrary function of  $x$ . The final solution is

$$x + y + z = y^2 \phi(x).$$

It sometimes happens that equations not belonging to the above class are reducible to it by a transformation.

Ex. 3. Given  $\frac{d^2 z}{dx dy} = x^2 + y^2$ .

Let  $\frac{dz}{dx} = w$ , then we have  $\frac{dw}{dy} = x^2 + y^2$ , whence integrating with respect to  $y$ , and adding an arbitrary function of  $x$ ,

$$w = x^2 y + \frac{y^3}{3} + \phi(x).$$

Restoring to  $w$  its value  $\frac{dz}{dx}$ , integrating with respect to  $x$ , and adding an arbitrary function of  $y$ , we have

$$z = \frac{x^3 y}{3} + \frac{y^3 x}{3} + \int \phi(x) dx + \psi(y).$$

Now  $\phi(x)$  being arbitrary,  $\int \phi(x) dx$  is also arbitrary, and may be represented by  $\chi(x)$ , whence

$$z = \frac{x^3 y + y^3 x}{3} + \chi(x) + \psi(y).$$

[See the *Supplementary Volume*, Chapter XXIV. Art. 1.]

*Linear partial differential equations of the first order.*

3. When there are but three variables,  $z$  dependent,  $x$  and  $y$  independent, the equations to be considered assume the form

$$P \frac{dz}{dx} + Q \frac{dz}{dy} = R,$$

$P$ ,  $Q$ , and  $R$  being given functions of  $x$ ,  $y$ ,  $z$ , or constant. This form we shall first consider.

Usually the differential coefficients  $\frac{dz}{dx}$  and  $\frac{dz}{dy}$  are represented by  $p$  and  $q$  respectively. The equation thus becomes

$$Pp + Qq = R \dots\dots\dots(1).$$

The mode of solution is due to Lagrange, and was first established by the following considerations.

Since  $z$  is a function of  $x$  and  $y$ , we have

$$dz = p dx + q dy.$$

Hence eliminating  $p$  between the above and the given equation, we have

$$Pdz - Rdx = q (Pdy - Qdx).$$

Suppose in the first place that  $Pdz - Rdx$  is the exact differential of a function  $u$ , and  $Pdy - Qdx$  the exact differential of a function  $v$ , then we have

$$du = q dv.$$

Now the first member being an exact differential, the second must also be such. This requires that  $q$  should be a function of  $v$ , but does not limit the form of the function. Represent it by  $\phi'(v)$ , then we have  $du = \phi'(v) dv$ , whence

$$u = \phi(v) \dots\dots\dots(2).$$

The functions  $u$  and  $v$  are determined by integrating the equations

$$Pdz - Rdx = 0, \quad Pdy - Qdx = 0,$$

symmetrically expressible in the form

$$\frac{dx}{P} = \frac{dy}{Q} = \frac{dz}{R} \dots\dots\dots(3),$$

and of which the solution, Chap. XIII. Art. 5, assumes the form

$$u = a, \quad v = b \dots\dots\dots(4),$$

$a$  and  $b$  being arbitrary constants.

Dismissing the particular hypothesis above employed, Lagrange then proves that if in any case we can obtain two integrals of the system (3) in the forms (4), then  $u = \phi(v)$  will satisfy the partial differential equation, in perfect independence of the form of the function  $\phi$ .

We shall adopt a somewhat different course. We shall first establish a general Rule for the formation of a partial differential equation whose primitive is of the form  $u = \phi(v)$ ,  $u$  and  $v$  being given functions of  $x$ ,  $y$ , and  $z$ . Upon the solution of this direct problem we shall ground the solution of the inverse problem of ascending from the partial differential equation to its primitive.

**PROPOSITION.** *A primitive equation of the form  $u = \phi(v)$ , where  $u$  and  $v$  are given functions of  $x$ ,  $y$ ,  $z$ , gives rise to a partial differential equation of the form*

$$Pp + Qq = R \dots\dots\dots(5),$$

where  $P$ ,  $Q$ ,  $R$  are functions of  $x$ ,  $y$ ,  $z$ .

Before demonstrating this proposition we stop to observe that the form  $u = \phi(v)$  is equivalent to the form

$$f(u, v) = 0,$$

$f(u, v)$  denoting an arbitrary function of  $u$  and  $v$ . For solving the latter equation we have  $u = \phi(v)$ .

It is also equivalent to

$$F\{x, y, z, \phi(v)\} = 0,$$

$\phi$  being an arbitrary, but  $F$  a definite functional symbol.

For solving the latter equation with respect to  $\phi(v)$  we have a result of the form

$$\phi(v) = F_1(x, y, z), \text{ or } \phi(v) = u$$

on representing  $F_1(x, y, z)$  by  $u$ . Thus the proposition affirmed amounts to this, viz. that any equation between  $x$ ,  $y$ , and  $z$  which involves an arbitrary function will give rise to a linear partial differential equation of the first order.

Differentiating the primitive  $u = \phi(v)$ , first with respect to  $x$ , secondly with respect to  $y$ , we have

$$\begin{aligned} \frac{du}{dx} + \frac{du}{dz} p &= \phi'(v) \left( \frac{dv}{dx} + \frac{dv}{dz} p \right), \\ \frac{du}{dy} + \frac{du}{dz} q &= \phi'(v) \left( \frac{dv}{dy} + \frac{dv}{dz} q \right). \end{aligned}$$

Eliminating  $\phi'(v)$  by dividing the second equation by the first, we have

$$\frac{\frac{du}{dy} + \frac{du}{dz} q}{\frac{du}{dx} + \frac{du}{dz} p} = \frac{\frac{dv}{dy} + \frac{dv}{dz} q}{\frac{dv}{dx} + \frac{dv}{dz} p},$$

or, on clearing of fractions,

$$\begin{aligned} \left( \frac{du}{dy} \frac{dv}{dz} - \frac{du}{dz} \frac{dv}{dy} \right) p + \left( \frac{du}{dz} \frac{dv}{dx} - \frac{du}{dx} \frac{dv}{dz} \right) q \\ = \frac{du}{dx} \frac{dv}{dy} - \frac{du}{dy} \frac{dv}{dx} \dots\dots\dots(6). \end{aligned}$$

Now this is a partial differential equation of the form (5). For  $u$  and  $v$  being given functions of  $x$ ,  $y$  and  $z$ , the coefficients of  $p$  and  $q$ , as well as the second member, are known. The proposition is therefore proved.

As an illustration, we have in Ex. 1, Art. 1,  $u = x - lz$ ,  $v = y - mz$ , whence

$$\begin{aligned} \frac{du}{dx} = 1, \quad \frac{du}{dy} = 0, \quad \frac{du}{dz} = -l, \\ \frac{dv}{dx} = 0, \quad \frac{dv}{dy} = 1, \quad \frac{dv}{dz} = -m. \end{aligned}$$

Substituting these values in (6) there results,

$$lp + mq = 1,$$

which agrees with the result before obtained.

4. The general equation (6), of which the above theorem is a direct consequence, has been established by the direct elimination of the arbitrary function. But the same result may also be established in the following manner, which has the advantage of shewing the real nature of the dependence of the coefficients  $P$ ,  $Q$ ,  $R$  upon the given functions  $u$  and  $v$ .

[See a Note at the end of the volume.]

Differentiating the equation  $u = \phi(v)$  with respect to all the variables, we have

$$\frac{du}{dx} dx + \frac{du}{dy} dy + \frac{du}{dz} dz = \phi'(v) \left( \frac{dv}{dx} dx + \frac{dv}{dy} dy + \frac{dv}{dz} dz \right) \dots (7),$$

and as this equation is to hold true independently of the form of the function  $\phi(v)$ , and therefore of the form of the derived function  $\phi'(v)$ , we must have

$$\left. \begin{aligned} \frac{du}{dx} dx + \frac{du}{dy} dy + \frac{du}{dz} dz &= 0 \\ \frac{dv}{dx} dx + \frac{dv}{dy} dy + \frac{dv}{dz} dz &= 0 \end{aligned} \right\} \dots \dots \dots (8),$$

whence we find

$$\frac{\frac{dx}{\frac{du}{dy} \frac{dv}{dz} - \frac{du}{dz} \frac{dv}{dy}}}{\frac{dy}{\frac{du}{dz} \frac{dv}{dx} - \frac{du}{dx} \frac{dv}{dz}}} = \frac{\frac{dy}{\frac{du}{dz} \frac{dv}{dx} - \frac{du}{dx} \frac{dv}{dz}}}{\frac{dz}{\frac{du}{dx} \frac{dv}{dy} - \frac{du}{dy} \frac{dv}{dx}}} \dots (9).$$

Introducing now the condition that  $z$  is the dependent,  $x$  and  $y$  the independent variables, we have

$$pdx + qdy = dz.$$

To eliminate the differentials, let the terms of this equation be divided by the respectively equal members of (9), and we have

$$\begin{aligned} \left( \frac{du}{dy} \frac{dv}{dz} - \frac{du}{dz} \frac{dv}{dy} \right) p + \left( \frac{du}{dz} \frac{dv}{dx} - \frac{du}{dx} \frac{dv}{dz} \right) q \\ = \frac{du}{dx} \frac{dv}{dy} - \frac{du}{dy} \frac{dv}{dx} \dots\dots\dots (10), \end{aligned}$$

which agrees with (6).

Now if in the above general form we represent as before the coefficient of  $p$  by  $P$ , that of  $q$  by  $Q$ , and the second member by  $R$ , we see from (9) that  $P$ ,  $Q$ ,  $R$  are proportional to  $dx$ ,  $dy$  and  $dz$ , in the system (8). But that system is precisely the same as we should obtain by differentiating the equations

$$u = a, \quad v = b,$$

$a$  and  $b$  being arbitrary constants. Hence, the partial differential equation whose complete primitive is  $u = \phi(v)$ , may be formed by the following simple rule.

**RULE.** *Forming the equations  $u = a$ ,  $v = b$ , where  $a$  and  $b$  are arbitrary constants, differentiate them, and determine the ratios of  $dx$ ,  $dy$ ,  $dz$  in the form*

$$\frac{dx}{P} = \frac{dy}{Q} = \frac{dz}{R} \dots\dots\dots (11).$$

*Then will  $Pp + Qq = R$  be the differential equation required.*

Or, the Rule may more briefly be stated thus. *Eliminate  $dx$ ,  $dy$ ,  $dz$  between the three equations,*

$$du = 0, \quad dv = 0, \quad dz - p dx - q dy = 0 \dots\dots\dots (12).$$

It is worth while to notice that the partial differential equation here presents itself, like many other results of analysis, in the form of a *determinant*.

**Ex.** The functional equation of surfaces of revolution, the axis passing through the origin, is

$$lx + my + nz = \phi(x^2 + y^2 + z^2);$$

their partial differential equation is required.

Here, proceeding according to the Rule, we have

$$l dx + m dy + n dz = 0,$$

$$x dx + y dy + z dz = 0,$$

whence 
$$\frac{dx}{mz - ny} = \frac{dy}{nx - lz} = \frac{dz}{ly - mx}.$$

The partial differential equation therefore is

$$(mz - ny)p + (nx - lz)q = ly - mx.$$

[See the *Supplementary Volume*, Chapter XXIV. Art. 2.]

5. We proceed in the second place to apply the above results to the inverse problem of solution.

From what has been said of the origin of partial differential equations of the form  $Pp + Qq = R$  it is evident that their solution will be effected by the following rule.

RULE. *Form the system of ordinary differential equations*

$$\frac{dx}{P} = \frac{dy}{Q} = \frac{dz}{R} \dots\dots\dots (13),$$

*and express their integrals in the forms  $u = a$ ,  $v = b$ ; then will the equation  $u = f(v)$ , where  $f$  is a symbol of arbitrary functionality, express the solution required.*

For, setting out from the assumed primitive,  $u = f(v)$ , we should, by the application of the previous and direct Rule, be led to the partial differential equation in question.

The difficulty of the process consisting therefore solely in the integration of the system of *ordinary* differential equations (13), is referred to the methods of the last Chapter.

Ex. 1. Given  $xp + yq = nz$ .

Here, the system of *ordinary* differential equations is

$$\frac{dx}{x} = \frac{dy}{y} = \frac{dz}{nz},$$

and the variables therein are separated. The integrals may obviously be expressed in the forms

$$\frac{y}{x} = c, \quad \frac{z}{x^n} = c'.$$

Hence, the required solution is

$$\frac{z}{x^n} = \phi \left( \frac{y}{x} \right),$$

indicating that  $z$  is a homogeneous function of  $x$  and  $y$  of the  $n^{\text{th}}$  degree.

Ex. 2. Given  $(mz - ny)p + (nx - lz)q = ly - mx$ .

Here the system of ordinary differential equations is

$$\frac{dx}{mz - ny} = \frac{dy}{nx - lz} = \frac{dz}{ly - mx}.$$

From these we readily deduce

$$l dx + m dy + n dz = 0, \quad x dx + y dy + z dz = 0,$$

the integrals of which are

$$lx + my + nz = a, \quad x^2 + y^2 + z^2 = b,$$

the final solution is therefore

$$lx + my + nz = \phi(x^2 + y^2 + z^2).$$

Ex. 3. Given  $(y^3x - 2x^4) \frac{d\mu}{dx} + (2y^4 - x^3y) \frac{d\mu}{dy} = 9(x^3 - y^3)\mu$ .

This is the partial differential equation on the solution of which would depend the determination of the general integrating factor of the equation  $(x^3y - 2y^4) dx + (y^3x - 2x^4) dy = 0$ .  
Chap. IV. Art. 3.

The system of ordinary differential equations is

$$\frac{dx}{y^3x - 2x^4} = \frac{dy}{2y^4 - x^3y} = \frac{d\mu}{9(x^3 - y^3)\mu} \dots\dots\dots(a).$$

The first equation of the system is

$$(x^3y - 2y^4) dx + (y^3x - 2x^4) dy = 0,$$

and of this the complete solution is

$$\frac{x}{y^2} + \frac{y}{x^2} = c.$$

We may also deduce from (a)

$$3 \left( \frac{dx}{x} + \frac{dy}{y} \right) + \frac{d\mu}{\mu} = 0,$$

of which the complete primitive is

$$x^3 y^3 \mu = c'.$$

Hence the solution of the partial differential equation is

$$\mu = \frac{1}{x^3 y^3} \phi \left( \frac{x}{y^2} + \frac{y}{x^2} \right);$$

and this agrees with the result obtained by other considerations in the Chapter referred to.

We may note that in this, as in all similar cases, the differential equation whose integrating factor is sought, presents itself as one of the equations of the system on whose solution the *complete* determination of the factor rests.

To complete the theory of the linear partial differential equation  $Pp + Qq = R$  it ought to be shewn that the solution  $u = f(v)$ , or as it may be expressed,

$$F(u, v) = 0 \dots\dots\dots(14),$$

includes every possible solution.

Let  $\chi(x, y, z) = 0$ , or for simplicity  $\chi = 0$ , represent *any* particular solution. Differentiating, we have

$$\frac{d\chi}{dx} + \frac{d\chi}{dz} p = 0, \quad \frac{d\chi}{dy} + \frac{d\chi}{dz} q = 0,$$

and substituting the values of  $p$  and  $q$  hence derived in the given equation

$$P \frac{d\chi}{dx} + Q \frac{d\chi}{dy} + R \frac{d\chi}{dz} = 0.$$

Similar equations being obtained from the particular integrals  $u = a$ ,  $v = b$ , we have, on eliminating  $P$ ,  $Q$ ,  $R$ ,

$$\begin{aligned} \frac{d\chi}{dx} \left( \frac{du}{dy} \frac{dv}{dz} - \frac{du}{dz} \frac{dv}{dy} \right) + \frac{d\chi}{dy} \left( \frac{du}{dz} \frac{dv}{dx} - \frac{du}{dx} \frac{dv}{dz} \right) \\ + \frac{d\chi}{dz} \left( \frac{du}{dx} \frac{dv}{dy} - \frac{du}{dy} \frac{dv}{dx} \right) = 0 \dots\dots(15). \end{aligned}$$

Now suppose the forms of  $u$  and  $v$  to be

$$u = \phi(x, y, z), \quad v = \psi(x, y, z) \dots \dots \dots (16),$$

$\phi(x, y, z)$  and  $\psi(x, y, z)$  being given functions. From these two equations some two of the quantities  $x, y, z$  may be determined as functions of the other and of  $u$  and  $v$ . Suppose  $x$  and  $y$  thus determined as functions of  $z, u$ , and  $v$ ; then by substitution  $\chi(x, y, z)$  becomes a function of  $z, u$ , and  $v$ , and we may write

$$\chi(x, y, z) = \chi_1(z, u, v).$$

Hence we find

$$\frac{d\chi}{dx} = \frac{d\chi_1}{du} \frac{du}{dx} + \frac{d\chi_1}{dv} \frac{dv}{dx},$$

$$\frac{d\chi}{dy} = \frac{d\chi_1}{du} \frac{du}{dy} + \frac{d\chi_1}{dv} \frac{dv}{dy},$$

$$\frac{d\chi}{dz} = \frac{d\chi_1}{du} \frac{du}{dz} + \frac{d\chi_1}{dv} \frac{dv}{dz} + \frac{d\chi_1}{dz}.$$

Substituting these in (15) and reducing, we have

$$\frac{d\chi_1}{dz} \left( \frac{du}{dx} \frac{dv}{dy} - \frac{du}{dy} \frac{dv}{dx} \right) = 0 \dots \dots \dots (17).$$

But, were the second factor of the first member equal to 0,  $u$  would be a *definite* function of  $v$  and  $z$  (Chap. II. Art. 1) and the equations (16) could not determine  $x$  and  $y$  as by hypothesis they do. We have then  $\frac{d\chi_1}{dz} = 0$ , whence  $\chi_1$  does not involve  $z$ . Thus,  $\chi$  being expressible as a function of  $u$  and  $v$ , the equation  $\chi = 0$  is included in the general form (14).

[See the *Supplementary Volume*, Chapter XXIV. Art. 3.]

6. The above theory may be obviously extended to partial differential equations of the first order and degree involving any number of variables.

where  $p_1, p_2 \dots p_n$  are the several first differential coefficients of  $z$ . And now eliminating the differentials  $dx_1, dx_2, \dots dx_n, dz$  from (20) and (21) by division, we have

$$P_1 p_1 + P_2 p_2 \dots + P_n p_n = R \dots \dots \dots (22),$$

for the partial differential equation sought.

Conversely, to integrate the above equation it is only necessary to form and to integrate the system (20). Representing the integrals of that system in the forms

$$u = a, \quad v_1 = b_1, \quad v_2 = b_2, \dots v_{n-1} = b_{n-1},$$

the final solution will be

$$u = \phi(v_1, v_2, \dots v_{n-1}) \dots \dots \dots (23).$$

This solution may also be put in the form

$$\Phi(u, v_1, v_2, \dots v_{n-1}) = 0 \dots \dots \dots (24).$$

Ex.  $(y + z + t) \frac{dt}{dx} + (z + x + t) \frac{dt}{dy} + (x + y + t) \frac{dt}{dz} = x + y + z.$

Lagrange, *Mémoires de l'Académie Royale de Berlin*, 1779, p. 152.

Here the auxiliary system of equations is

$$\frac{dx}{y + z + t} = \frac{dy}{z + x + t} = \frac{dz}{x + y + t} = \frac{dt}{x + y + z},$$

which is reducible to the form

$$\frac{dt - dx}{x - t} = \frac{dt - dy}{y - t} = \frac{dt - dz}{z - t} = \frac{dx + dy + dz + dt}{3(x + y + z + t)},$$

each term being now an exact differential. The system of integrals will evidently be

$$\frac{c_1}{x - t} = \frac{c_2}{y - t} = \frac{c_3}{z - t} = (x + y + z + t)^{\frac{1}{3}}.$$

Or, representing the function  $x + y + z + t$  by  $S$ ,

$$S^{\frac{1}{3}}(x - t) = c_1, \quad S^{\frac{1}{3}}(y - t) = c_2, \quad S^{\frac{1}{3}}(z - t) = c_3.$$

Whence the complete integral symmetrically exhibited will be

$$\Phi \left\{ S^{\frac{1}{3}}(x-t), S^{\frac{1}{3}}(y-t), S^{\frac{1}{3}}(z-t) \right\} = 0.$$

The solution of all partial differential equations of the form

$$X_1 \frac{dz}{dx_1} + X_2 \frac{dz}{dx_2} \dots + X_n \frac{dz}{dx_n} = Z,$$

where  $X_1, X_2, \dots, X_n$  and  $Z$  are any linear functions of the variables  $x_1, x_2, \dots, x_n, z$ , may be completely effected.

For it depends on the solution of the system of ordinary differential equations

$$\frac{dx_1}{X_1} = \frac{dx_2}{X_2} \dots = \frac{dx_n}{X_n} = \frac{dz}{Z},$$

which has been fully discussed in Chap. XIII.

Hesse has integrated the still more general equation which, according to the above notation, would present itself in the form

$$\begin{aligned} X_1 \frac{dz}{dx_1} + X_2 \frac{dz}{dx_2} \dots + X_n \frac{dz}{dx_n} \\ + X_{n+1} \left( x_1 \frac{dz}{dx_1} + x_2 \frac{dz}{dx_2} \dots + x_n \frac{dz}{dx_n} - z \right) = X_{n+2}, \end{aligned}$$

where  $X_1, X_2, \dots, X_{n+2}$  are any linear functions of the variables. (Crelle, Tom. xxv. p. 171.)

[See the *Supplementary Volume*, Chapter xxiv. Arts. 4...7.]

*Non-linear equations of the first order with three variables.*

7. Partial differential equations of the first order with two independent variables  $x, y$ , and one dependent variable  $z$ , have for their typical form

$$F(x, y, z, p, q) = 0 \dots \dots \dots (1).$$

Those which are linear with respect to  $p$  and  $q$ , we have considered apart. Those which are non-linear we proceed to

consider. The genesis of an equation of this class from a complete primitive involving two arbitrary constants has been illustrated in Ex. 2, Art. 1; and the mode is general. From a given primitive, involving  $x, y, z$  with two arbitrary constants, and from its two derived equations of the first order formed by differentiating with respect to  $x$  and  $y$  respectively, it is possible to eliminate both the constants. The result is a partial differential equation of the first order. Conversely the integration of such an equation consists mainly in the discovery of its complete primitive—not that this is its only form of solution, but because out of it all other forms may be developed. From the complete primitive involving arbitrary constants arise, 1st, the general primitive involving arbitrary functions; 2ndly, the singular solution. The terminology of Lagrange is here adopted. (*Calcul des Fonctions, Leçon XX.*)

*To deduce the complete primitive of a partial differential equation of the form  $F(x, y, z, p, q) = 0$ .*

The existence of a primitive relation between  $x, y, z$  involves the supposition that the equation

$$dz = p dx + q dy \dots \dots \dots (2),$$

should satisfy the condition of integrability,

$$\left(\frac{dp}{dy}\right) = \left(\frac{dq}{dx}\right) \dots \dots \dots (3),$$

where  $\left(\frac{dp}{dy}\right)$  represents the differential coefficient of  $p$  with respect to  $y$  on the assumption that  $p$  is expressed as a function of  $x$  and  $y$ , and  $\left(\frac{dq}{dx}\right)$  the differential coefficient of  $q$  with respect to  $x$ , on a similar assumption as to the expression of  $q$ . Now regarding  $p$  for the sake of greater generality as a function of  $x, y, z$ ,  $z$  being at the same time an unknown function of  $x$  and  $y$ , we have

$$\begin{aligned} \left(\frac{dp}{dy}\right) &= \frac{dp}{dy} + \frac{dp}{dz} \frac{dz}{dy} \\ &= \frac{dp}{dy} + q \frac{dp}{dz}. \end{aligned}$$

Again, suppose that by means of the given differential equation,  $q$  may be expressed as a function of  $x, y, z, p$ . Regarding in such expression  $z$  as a function of  $x, y$ , and  $p$  as a function of  $x, y$ , and  $z$ , we have

$$\begin{aligned}\left(\frac{dq}{dx}\right) &= \frac{dq}{dx} + \frac{dq}{dz} \frac{dz}{dx} + \frac{dq}{dp} \left(\frac{dp}{dx} + \frac{dp}{dz} \frac{dz}{dx}\right), \\ &= \frac{dq}{dx} + \frac{dq}{dz} p + \frac{dq}{dp} \frac{dp}{dx} + \frac{dq}{dp} \frac{dp}{dz} p.\end{aligned}$$

Substituting these values in (3), we have on transposition

$$-\frac{dq}{dp} \frac{dp}{dx} + \frac{dp}{dy} + \left(q - p \frac{dq}{dp}\right) \frac{dp}{dz} = \frac{dq}{dx} + p \frac{dq}{dz} \dots\dots\dots(4).$$

Now the coefficients  $-\frac{dq}{dp}$ ,  $q - p \frac{dq}{dp}$ , and the second member  $\frac{dq}{dx} + p \frac{dq}{dz}$  being known functions of  $x, y, z, p$ , since  $q$  as determined by the given equation is such, the above presents itself as a linear partial differential equation of the first order in which  $p$  is the dependent and  $x, y, z$  the independent variables.

Applying therefore Lagrange's process, Art. 6, we have the auxiliary system

$$\frac{dx}{-\frac{dq}{dp}} = dy = \frac{dz}{q - p \frac{dq}{dp}} = \frac{dp}{\frac{dq}{dx} + p \frac{dq}{dz}} \dots\dots\dots(5);$$

and this, it is to be observed, is a system of *ordinary* differential equations between  $x, y, z$ , and  $p$ . It may further be noted that while it has been formed in order to secure the integrability of the equation  $dz = p dx + q dy$ , it also includes that equation. For it gives

$$dz = \left(q - p \frac{dq}{dp}\right) dy = p dx + q dy,$$

since by the equation of the first and second members

$$-\frac{dq}{dp} dy = dx.$$

Accordingly if from the system (5) we can deduce a value of  $p$  involving an arbitrary constant, that value together with the corresponding value of  $q$  drawn from the given equation will render the equation  $dz = p dx + q dy$  integrable. Effecting the integration we shall obtain an equation between  $x, y, z$  and two arbitrary constants which will constitute a complete primitive.

We say *a* and not *the* complete primitive, because the system (5) may furnish more than one value of  $p$  involving an arbitrary constant, and so give occasion to deduce more than one complete primitive. Lagrange had indeed proposed to employ the general value of  $p$  involving arbitrary functions, furnished by the solution of the partial differential equation (4). The sufficiency of a value involving only an arbitrary constant was remarked by Charpit and subsequently recognised by Lagrange.

The practical rule for the discovery of a complete primitive of the equation  $F(x, y, z, p, q) = 0$  is therefore the following. *Express  $q$  in terms of  $x, y, z, p$ . Substitute this value in the auxiliary system (5), and deduce by integration a value of  $p$  involving an arbitrary constant. Substitute that value of  $p$  with the corresponding value of  $q$  in the equation  $dz = p dx + q dy$ , also included in the auxiliary system (5), and again integrate.*

Ex. 1. Required a complete primitive of the equation  $z = pq$ .

Substituting  $\frac{z}{p}$  for  $q$ , the system (5) becomes

$$\frac{p^2 dx}{z} = dy = \frac{p dz}{2z} = dp.$$

The equation  $dp = dy$  gives  $p = y + a$ , whence  $q = \frac{z}{y + a}$ .

Therefore  $dz = (y + a) dx + \frac{z}{y + a} dy$ ,

of which the integral is

$$z = (y + a)(x + b) \dots\dots\dots (6),$$

$a$  and  $b$  being arbitrary constants. This then is a complete primitive.

Another will be found by employing the equation

$$\frac{pdz}{2z} = dp;$$

integrating which, we have

$$p = cz^{\frac{1}{2}}, \quad q = \frac{z^{\frac{1}{2}}}{c},$$

whence

$$dz = cz^{\frac{1}{2}} dx + \frac{z^{\frac{1}{2}}}{c} dy.$$

Integrating, we find

$$2z^{\frac{1}{2}} = cx + \frac{1}{c}y + e,$$

or

$$z = \frac{(cx + \frac{y}{c} + e)^2}{4} \dots\dots\dots(7),$$

$e$  being a new arbitrary constant. It will be found on trial that both (6) and (7) satisfy the equation  $z = pq$ .

8. PROP. *Given a complete primitive of a partial differential equation of the first order, to deduce the general primitive and the singular solution.*

Expressing the complete primitive in the form

$$z = f(x, y, a, b) \dots\dots\dots(8),$$

$a$  and  $b$  being its arbitrary constants, the partial differential equation is itself obtained by eliminating  $a$  and  $b$  between the above equation and the derived equations

$$p = \frac{df(x, y, a, b)}{dx}, \quad q = \frac{df(x, y, a, b)}{dy},$$

or, as we may for brevity write,

$$p = \frac{df}{dx}, \quad q = \frac{df}{dy} \dots\dots\dots(9).$$

Now reasoning as in Chap. VIII., the effect of the elimination will be the same if  $a$  and  $b$ , instead of being constants, are

made functions of  $x$  and  $y$ , so determined as to preserve to the equations (9) their actual form. But  $a$  and  $b$  being made variable, we have

$$p = \frac{df}{dx} + \frac{df}{da} \frac{da}{dx} + \frac{df}{db} \frac{db}{dx},$$

$$q = \frac{df}{dy} + \frac{df}{da} \frac{da}{dy} + \frac{df}{db} \frac{db}{dy}.$$

Hence the equations for determining  $a$  and  $b$  are

$$\frac{df}{da} \frac{da}{dx} + \frac{df}{db} \frac{db}{dx} = 0 \dots\dots\dots(10),$$

$$\frac{df}{da} \frac{da}{dy} + \frac{df}{db} \frac{db}{dy} = 0 \dots\dots\dots(11).$$

Now this system may be satisfied in two distinct ways,

1st by assuming

$$\frac{df}{da} = 0, \quad \frac{df}{db} = 0 \dots\dots\dots(12).$$

The values of  $a$  and  $b$  hence found lead, on substitution in the complete primitive, to that solution which Lagrange terms singular.

2ndly, Supposing  $\frac{df}{da}$  and  $\frac{df}{db}$  not to vanish, we have, on elimination of them from (10), (11),

$$\frac{da}{dx} \frac{db}{dy} - \frac{da}{dy} \frac{db}{dx} = 0 \dots\dots\dots(13).$$

Now this supposes either, 1st, that  $a$  and  $b$  are constant, which leads us back to the complete primitive; or, 2ndly, that  $b$  is an arbitrary function of  $a$ . Chap. II. Art. 1. Again, multiplying (10) by  $dx$  and (11) by  $dy$ , and adding, we have

$$\frac{df}{da} da + \frac{df}{db} db = 0 \dots\dots\dots(14).$$

Thus the system (10), (11) is now replaced by the system (13), (14).

Making then, in accordance with (13),  $b = \phi(a)$ , the expression for  $z$  in (8) becomes

$$z = f\{x, y, a, \phi(a)\},$$

while (14) becomes

$$\frac{d}{da} f\{x, y, a, \phi(a)\} = 0.$$

And these together constitute what Lagrange terms the *general primitive*. To apply them it is only necessary to give a particular form to  $\phi(a)$ , and then eliminate  $a$ . Hence the following theorem.

**THEOREM.** *A complete primitive of a partial differential equation of the first order being expressed in the form*

$$z = f(x, y, a, b) \dots\dots\dots(15),$$

*the general primitive will be obtained by eliminating  $a$  between the equations*

$$\left. \begin{aligned} z &= f\{x, y, a, \phi(a)\} \\ 0 &= \frac{df\{x, y, a, \phi(a)\}}{da} \end{aligned} \right\} \dots\dots\dots(16),$$

*the singular solution, by eliminating  $a$  and  $b$  between (15) and the equations*

$$\frac{df(x, y, a, b)}{da} = 0, \quad \frac{df(x, y, a, b)}{db} = 0 \dots\dots\dots(17).$$

It will be observed that the process for obtaining the general primitive is virtually equivalent to that by which we should seek the envelope of the surfaces defined by the corresponding complete primitive, the constants  $a$  and  $b$  being treated as variable parameters connected by an arbitrary relation, while the process for obtaining the singular solution is that by which we should seek the envelope of (15), supposing  $a$  and  $b$  to be independent parameters.

Thus, of the system of solutions which consists of a *complete* primitive, a *general* primitive, and a singular solution, the complete primitive must be regarded as forming the basis, and the system itself geometrically interpreted includes the surfaces represented by the complete primitive together with the whole of their possible envelopes.

Ex. To deduce the general primitive and singular solution of the equation  $z = pq$ .

A complete primitive being

$$z = (y + a)(x + b) \dots\dots\dots (a),$$

the corresponding general primitive will be expressed by the system

$$\left. \begin{aligned} z &= (y + a) \{x + \phi(a)\} \\ 0 &= x + \phi(a) + (y + a) \phi'(a) \end{aligned} \right\} \dots\dots\dots (b),$$

from which  $a$  must be eliminated when the form of  $\phi(a)$  is assigned. Another form of the complete primitive being

$$z = \frac{(cx + \frac{y}{c} + e)^2}{4} \dots\dots\dots (c),$$

the corresponding form of the general primitive will be

$$\left. \begin{aligned} z &= \frac{1}{4} \left\{ cx + \frac{y}{c} + \psi(c) \right\}^2 \\ 0 &= x - \frac{y}{c^2} + \psi'(c) \end{aligned} \right\} \dots\dots\dots (d),$$

from which  $c$  must be eliminated when the form of  $\psi(c)$  is assigned.

To deduce the singular solution, we have from (a),

$$\frac{dz}{da} = x + b = 0,$$

$$\frac{dz}{db} = y + a = 0.$$

Hence,  $b = -x$ ,  $a = -y$  which, substituted in (a), gives  $z = 0$ , a singular solution. The same result is deducible from (c).

9. In the last example, two complete primitives, two corresponding forms of general primitive, and one common form of singular solution are presented. Two systems of solution appear, and the question arises: Does either system suffice alone? The answer is given in the following theorem.

**THEOREM.** *All possible solutions of a partial differential equation of the first order, are virtually contained in the system consisting of a single complete primitive, with the derived general primitive and singular solution.*

As before, we shall represent the proposed differential equation and its given complete primitive in the forms,

$$F(x, y, z, p, q) = 0 \dots\dots\dots (18),$$

$$z = f(x, y, a, b) \dots\dots\dots (19).$$

We shall also represent the form,

$$z = \chi(x, y) \dots\dots\dots (20),$$

some solution of (18), of which nothing more is known than that it is a solution. We are to shew that such solution is included in the system of solutions of which the common primitive (19) constitutes the basis.

If we represent for brevity the values of  $z$  in (19) and (20) by  $f$  and  $\chi$  respectively, we shall have, since both are solutions of (18),

$$F\left(x, y, f, \frac{df}{dx}, \frac{df}{dy}\right) = 0 \dots\dots\dots (21),$$

$$F\left(x, y, \chi, \frac{d\chi}{dx}, \frac{d\chi}{dy}\right) = 0 \dots\dots\dots (22).$$

From the form of the above equations it appears that if  $a$  and  $b$  are so determined as to satisfy two of the conditions,

$$f = \chi, \quad \frac{df}{dx} = \frac{d\chi}{dx}, \quad \frac{df}{dy} = \frac{d\chi}{dy} \dots\dots\dots (23),$$

they will satisfy the third. For suppose they satisfy the first two, then the system (21), (22) may be expressed in the form

$$F\left(x, y, \chi, \frac{d\chi}{dx}, \frac{df}{dy}\right) = 0, \quad F\left(x, y, \chi, \frac{d\chi}{dx}, \frac{d\chi}{dy}\right) = 0 \dots (24),$$

in which the truth of the third equation of (23) is involved.

Now, as (19) satisfies (18) whatever constant values we assign to  $a$  and  $b$ , it still will do so if, *after* the differentiations by which  $\frac{df}{dx}$  and  $\frac{df}{dy}$  are found, we substitute for  $a$  and  $b$  any functions of  $x$  and  $y$ .

But  $a$  and  $b$  can be determined so as to satisfy two conditions. Hence they can be determined so as to satisfy the system (23). Differentiating the equation  $f = \chi$  on the hypothesis that  $a$  and  $b$  are functions so determined, we have

$$\begin{aligned} \frac{df}{dx} + \frac{df}{da} \frac{da}{dx} + \frac{df}{db} \frac{db}{dx} &= \frac{d\chi}{dx}, \\ \frac{df}{dy} + \frac{df}{da} \frac{da}{dy} + \frac{df}{db} \frac{db}{dy} &= \frac{d\chi}{dy}. \end{aligned}$$

Here,  $\frac{df}{dx}$ ,  $\frac{df}{dy}$  have the same values as in (23), being obtained by differentiating as if  $a$  and  $b$  were constant. Hence, reducing by (23), we have

$$\left. \begin{aligned} \frac{df}{da} \frac{da}{dx} + \frac{df}{db} \frac{db}{dx} &= 0 \\ \frac{df}{da} \frac{da}{dy} + \frac{df}{db} \frac{db}{dy} &= 0 \end{aligned} \right\} \dots \dots \dots (25).$$

But these are the equations (10), (11), Art. 8, by which the system of solutions founded upon the complete primitive is constructed.

The argument then is briefly this. If  $z = \chi(x, y)$  is a solution of the given partial differential equation, it is possible to determine  $a$  and  $b$  in the given complete primitive so as to satisfy the equations (23); therefore so as to satisfy the

equations (25); therefore so as to indicate a necessary inclusion of  $z = \chi(x, y)$  in the system which is founded upon the given complete primitive.

COR. 1. Hence the connexion of a given solution with a given complete primitive may be determined in the following manner. Adopting the foregoing notation, determine the values of  $a$  and  $b$  which satisfy the system (23). If those values are constant, the solution is a particular case of the complete primitive; if they are variable, but so that the one is a function of the other, the solution is a particular case of the general primitive; if they are variable and unconnected it is a singular solution.

COR. 2. Hence also any two systems of solutions founded upon distinct complete primitives are equivalent. For each is virtually composed of all possible particular solutions.

Ex. The equation  $z = pq$ , has for its complete primitive  $z = (x + a)(y + b)$ , and for a particular solution  $z = \frac{(y + x)^2}{4}$ . What is the connexion of this solution with the complete primitive?

We have by (23),

$$(x + a)(y + b) = \frac{(y + x)^2}{4},$$

$$y + b = \frac{y + x}{2}, \quad x + a = \frac{y + x}{2}.$$

These equations are not independent, the first being the product of the last two. Any two of them give

$$a = \frac{y - x}{2}, \quad b = \frac{x - y}{2},$$

whence  $b = -a$ . Thus, the values of  $a$  and  $b$  being variable, but such that  $b$  is a function of  $a$ , the proposed solution is a particular case of the general primitive.

Some general questions, but of minor importance, relating to the functional connexion of different forms of solution, will be noticed in the Exercises at the end of this Chapter.

In quitting this part of the subject, we may observe that there are two modes in which the questions it involves may be considered. The first consists in shewing that the gain of generality, which in Charpit's process accrues in the transition from the complete to the general primitive, is equal to that which Lagrange's original but far more difficult process secures by the employment of the general value of  $p$  drawn from (4), instead of a particular value drawn from its auxiliary system. The proof of this equivalence, as developed with more or less of completeness, by Lagrange and Poisson (*Lacroix*, Tom. II. p. 564, III. p. 705), and recently by Prof. De Morgan (*Cambridge Journal*, Vol. VII. p. 28), is, from its complexity, unsuitable to an elementary work. The other mode is that developed in the foregoing sections.

*Derivation of the singular solution from the differential equation.*

10. The complete primitive expresses  $z$  in terms of  $x, y, a, b$ . The differential equation expresses  $z$  in terms of  $x, y, p, q$ . Either is convertible into the other by means of the two equations derived from the complete primitive by differentiating with respect to  $x$  and  $y$  respectively. Hence it is not difficult to establish the two following equations,

$$\left. \begin{aligned} \frac{dz}{dp} &= \frac{\frac{dz}{da} \frac{d^2z}{dbdy} - \frac{dz}{db} \frac{d^2z}{dad y}}{\frac{d^2z}{dad x} \frac{d^2z}{dbdy} - \frac{d^2z}{dady} \frac{d^2z}{dbdx}} \\ \frac{dz}{dq} &= - \frac{\frac{dz}{da} \frac{d^2z}{dbdx} - \frac{dz}{db} \frac{d^2z}{dad x}}{\frac{d^2z}{dad x} \frac{d^2z}{dbdy} - \frac{d^2z}{dady} \frac{d^2z}{dbdx}} \end{aligned} \right\} \dots\dots\dots (26),$$

in the first members of which  $z$  is supposed to be expressed in terms of  $x, y, p, q$  by means of the differential equation, in the second members, in terms of  $x, y, a, b$  by means of the complete primitive.

Now the singular solution is deduced from the complete primitive by means of the equations

$$\frac{dz}{da} = 0, \quad \frac{dz}{db} = 0 \dots\dots\dots (27);$$

and it is evident from the form of (26), that this will generally involve the conditions

$$\frac{dz}{dp} = 0, \quad \frac{dz}{dq} = 0 \dots\dots\dots (28).$$

Such then will generally be the conditions for determining the singular solution from the differential equation.

The conditions (28) will not present themselves, should the denominator of the right-hand members of (26) vanish identically. But it may be shewn that in this case the conditions (27) do not lead to a singular solution. And analogy renders it probable that *whenever* the conditions (28) are satisfied the result, if it be a solution at all, will be a singular solution. The complete investigation of this point, however, would involve inquiries similar to those of Chapter VIII.

The Rule indicated is then *to eliminate  $p$  and  $q$  from the differential equation by means of the equations (28) thence derived.*

[See the *Supplementary Volume*, Chapter XXIV. Art. 8.]

11. The following geometrical applications are intended to illustrate the preceding sections.

Ex. 1. Required to determine the general equation of the family of surfaces in which the length of that portion of the normal which is intercepted between the surface and the plane  $x, y$ , is constant and equal to unity.

As the length of the intercept above described in any surface is  $z(1 + p^2 + q^2)^{\frac{1}{2}}$ , we have to solve the equation

$$z^2(1 + p^2 + q^2) = 1 \dots\dots\dots (a).$$

Hence  $q = (z^{-2} - 1 - p^2)^{\frac{1}{2}}$ , and the auxiliary system (5), Art. 7, becomes, on substitution and division by  $(z^{-2} - 1 - p^2)^{\frac{1}{2}}$ ,

$$\frac{dx}{p} = \frac{dy}{(z^{-2} - 1 - p^2)^{\frac{1}{2}}} = \frac{dz}{z^{-2} - 1} = -\frac{z^3 dp}{p} \dots\dots\dots (b).$$

From the last two members we have on integration

$$p = \frac{c(1-z^2)^{\frac{1}{2}}}{z}.$$

Substituting this, with the corresponding value of  $q$  derived from (a), in the equation  $dz = p dx + q dy$  we have

$$dz = \frac{c(1-z^2)^{\frac{1}{2}}}{z} dx + (1-c^2)^{\frac{1}{2}} \frac{(1-z^2)^{\frac{1}{2}}}{z} dy,$$

integrating which in the usual way, we find

$$(1-z^2)^{\frac{1}{2}} = -cx - (1-c^2)^{\frac{1}{2}}y - c',$$

or, changing the signs of  $c$  and  $c'$ ,

$$(1-z^2)^{\frac{1}{2}} = cx - (1-c^2)^{\frac{1}{2}}y + c' \dots\dots\dots (c),$$

which is a complete primitive. The corresponding form of the general primitive will be

$$\left. \begin{aligned} (1-z^2)^{\frac{1}{2}} &= cx - (1-c^2)^{\frac{1}{2}}y + \phi(c) \\ 0 &= x + c(1-c^2)^{-\frac{1}{2}}y + \phi'(c) \end{aligned} \right\} \dots\dots\dots (d),$$

from which  $c$  must be eliminated.

But another system of solutions exists; for from the first, third, and fourth members of (b) we may deduce

$$pdz + zdp + dx = 0,$$

whence  $pz + x = a$ , from which, and from the given equation determining  $p$  and  $q$ , we have to integrate

$$dz = \frac{a-x}{z} dx + \frac{\{1 - (a-x)^2 - z^2\}^{\frac{1}{2}}}{z} dy.$$

The result is

$$(x-a)^2 + (y-b)^2 + z^2 = 1 \dots\dots\dots (e),$$

a complete primitive. The corresponding general primitive is

$$\left. \begin{aligned} (x-a)^2 + \{y-\psi(a)\}^2 + z^2 &= 1 \\ x-a + \{y-\psi(a)\} \psi'(a) &= 0 \end{aligned} \right\} \dots\dots\dots (f).$$

To deduce the singular solution from the differential equation ( $\alpha$ ) we have

$$\frac{dz}{dp} = -p (1 + p^2 + q^2)^{-\frac{3}{2}} = 0, \quad \frac{dz}{dq} = -q (1 + p^2 + q^2)^{-\frac{3}{2}} = 0,$$

whence  $p = 0$ ,  $q = 0$ ; substituting which in ( $\alpha$ ) we find

$$z = \pm 1.$$

The above example illustrates the importance of obtaining, if possible, a choice of forms of the complete primitives. The second, of those above obtained, leads to the more interpretable results. It represents a sphere whose radius is unity and whose centre is in the plane  $x, y$ , while the derived general primitive represents the tubular surface generated by that sphere moving but not ceasing to obey the same conditions. The singular solution represents the two planes between which the motion would be confined. All these surfaces evidently satisfy the conditions of the problem.

Ex. 2. Required to determine a system of surfaces such that the area of any portion shall be in a constant ratio ( $m : 1$ ) to the area of its projection on the plane  $xy$ .

The differential equation is evidently

$$1 + p^2 + q^2 = m^2,$$

and it will readily be found that it has only one complete primitive, viz.

$$z = ax + \sqrt{(m^2 - a^2 - 1)} y + b.$$

Thus the general primitive is

$$z = ax + \sqrt{(m^2 - a^2 - 1)} y + \phi(a),$$

$$0 = x - \frac{a}{\sqrt{(m^2 - a^2 - 1)}} y + \phi'(a);$$

and this represents various systems of cones and other developable surfaces.

Similar but more interesting applications may be drawn from the problem of the determination of equally attracting surfaces.

12. Attention has already been directed to the different forms in which the solution of a non-linear equation may sometimes be presented. It may be added that linear equations admit generally of a duplex form of solution. The ordinary method gives directly the equation of the system of surfaces which they represent; Charpit's method leads to a form of solution which exhibits rather the mode of their genesis.

Ex. Lagrange's method presents the solution of the equation

$$(mz - ny) p + (nx - lz) q = ly - mx \dots\dots\dots(a),$$

in the form

$$lx + my + nz = \phi (x^2 + y^2 + z^2) \dots\dots\dots(b),$$

the known equation of surfaces of revolution whose axes pass through the origin of co-ordinates.

Charpit's method presents as the complete primitive of (a)

$$(x - cl)^2 + (y - cm)^2 + (z - cn)^2 = r^2 \dots\dots\dots(c),$$

$c$  and  $r$  being arbitrary constants. This is the equation of the generating sphere. The general primitive represents its system of possible envelopes.

These solutions are manifestly equivalent.

*Symmetrical and more general solution of partial differential equations of the first order.*

13. The method of Charpit labours under two defects. 1st, It supposes that from the given equation  $q$  can be expressed as a function of  $x, y, z, p$ ; 2ndly, It throws little light of analogy on the solution of equations involving *more* than two independent variables—a subject of fundamental importance in connexion with the highest class of researches on Theoretical Dynamics. We propose to supply these defects.

It will have been noted that Charpit's method consists in determining  $p$  and  $q$  as functions of  $x, y, z$ , which render the equation  $dz = pdx + qdy$  integrable. This determination presupposes the existence of two algebraic equations between  $x, y, z, p, q$ ; viz. 1st, the equation given, 2ndly, an equation obtained by integration and involving an arbitrary constant. Let us represent these equations by

$$F(x, y, z, p, q) = 0, \quad \Phi(x, y, z, p, q) = a \dots (29),$$

respectively. And let us now endeavour to obtain in a general manner the relation between the functions  $F$  and  $\Phi$ .

Simply differentiating with respect to  $x, y, z, p, q$ , and representing  $\frac{dF}{dx}$  by  $X$ ,  $\frac{d\Phi}{dx}$  by  $X'$ ,  $\frac{dF}{dp}$  by  $P$ ,  $\frac{d\Phi}{dp}$  by  $P'$ , &c. we have  $Xdx + Ydy + Zdz + Pdp + Qdq = 0$ ,

$$X'dx + Y'dy + Z'dz + P'dp + Q'dq = 0;$$

or, substituting  $pdx + qdy$  for  $dz$ ,

$$(X + pZ)dx + (Y + qZ)dy + Pdp + Qdq = 0 \dots (30),$$

$$(X' + pZ')dx + (Y' + qZ')dy + P'dp + Q'dq = 0 \dots (31).$$

But, representing for brevity  $\frac{d^2z}{dx^2}$ ,  $\frac{d^2z}{dxdy}$  and  $\frac{d^2z}{dy^2}$ , by  $r, s, t$ , respectively, we have

$$\left. \begin{aligned} dp &= rdx + sdy \\ dq &= sdx + tdy \end{aligned} \right\} \dots \dots \dots (32).$$

Substituting these values in (31) we have

$$(X' + pZ' + rP' + sQ')dx + (Y' + qZ' + sP' + tQ')dy = 0,$$

which, since  $dx$  and  $dy$  are independent, can only be satisfied by separately equating to 0 their coefficients. These furnish then the two equations

$$\left. \begin{aligned} -(X' + pZ') &= rP' + sQ' \\ -(Y' + qZ') &= sP' + tQ' \end{aligned} \right\} \dots \dots \dots (33).$$

Now these equations are of the same *form* as (32). They establish the same relations between the functions

$$-(X' + pZ'), -(Y' + qZ'), P', Q', \dots \dots \dots (34),$$

as (32) does between the differentials  $dp, dq, dx, dy$ .

It follows that if we give to  $dx$  and  $dy$ , which are arbitrary, the ratio of the last two of the functions (34) then will  $dp$  and  $dq$  have the ratio of the first two, so that the following will be a consistent scheme of relations, viz.

$$\frac{dx}{P'} = \frac{dy}{Q'} = -\frac{dp}{X' + pZ'} = -\frac{dq}{Y' + qZ'} \dots \dots \dots (35).$$

Now dividing the successive terms of (30) by the successive members of (35) we have

$$(X + pZ) P' + (Y + qZ) Q' - P (X' + pZ') - Q (Y' + qZ') = 0 \dots \dots (36).$$

This is the relation sought. It might be obtained by direct elimination by multiplying the equations of (33) by  $P$  and  $Q$  respectively, and the corresponding equations derived from (30) by  $P'$  and  $Q'$  respectively, and subtracting the sum of the former from the sum of the latter.

It is obvious too, and the remark is important, that we might pass directly from (30) to (36) by substituting for  $dx, dy, dp, dq$ , the functions of (34), and that this substitution is justified by the identity of relations established in (32) and (33).

If in (36) we substitute for  $X, Y$ , &c. their values, and transpose the second and third terms, we have

$$\begin{aligned} \left(\frac{dF}{dx} + p \frac{dF}{dz}\right) \frac{d\Phi}{dp} - \left(\frac{d\Phi}{dx} + p \frac{d\Phi}{dz}\right) \frac{dF}{dp} + \left(\frac{dF}{dy} + q \frac{dF}{dz}\right) \frac{d\Phi}{dq} \\ - \left(\frac{d\Phi}{dy} + q \frac{d\Phi}{dz}\right) \frac{dF}{dq} = 0 \dots \dots \dots (37). \end{aligned}$$

Such is the relation which connects the functions  $F$  and  $\Phi$ . When  $F$  is given it assumes the form of a linear partial differ-

ential equation of the first order for determining  $\Phi$ . If from its auxiliary system we can deduce any integral involving an arbitrary constant, and such that in conjunction with the given equation it enables us to determine  $p$  and  $q$  as functions of  $x, y, z$ , the subsequent integration of  $dz = p dx + q dy$  will lead to a form of the complete primitive.

14. Analogy now points out the method to be pursued for the solution of equations involving more than two independent variables.

PROP. To deduce the complete primitive of the partial differential equation

$$F(x_1, x_2, \dots x_n, z, p_1, p_2, \dots p_n) = 0 \dots \dots \dots (38),$$

where 
$$p_1 = \frac{dz}{dx_1}, \dots p_n = \frac{dz}{dx_n}.$$

In the first place we must seek to determine values of  $p_1, p_2, \dots p_n$  in terms of the primitive variables  $x_1, x_2, \dots x_n, z$ , such as will render integrable the equation

$$dz = p_1 dx_1 + p_2 dx_2 \dots + p_n dx_n \dots \dots \dots (39).$$

Suppose one of the equations requisite in conjunction with (38) for this determination to be

$$\Phi(x_1, x_2, \dots x_n, z, p_1, p_2, \dots p_n) = a_1 \dots \dots \dots (40).$$

Then representing the first members of (38) and (40) by their characteristics  $F$  and  $\Phi$ , differentiating, and substituting for  $dz$  its value given in (39), we have results which may be thus expressed,

$$\Sigma_i \left\{ \left( \frac{dF}{dx_i} + p_i \frac{dF}{dz} \right) dx_i + \frac{dF}{dp_i} dp_i \right\} = 0 \dots \dots \dots (41),$$

$$\Sigma_i \left\{ \left( \frac{d\Phi}{dx_i} + p_i \frac{d\Phi}{dz} \right) dx_i + \frac{d\Phi}{dp_i} dp_i \right\} = 0 \dots \dots \dots (42),$$

where  $\Sigma_i$  represents summation from  $i = 1$  to  $i = n$ .

But since  $p_i = \frac{dz}{dx_i}$ , we have

$$dp_i = \frac{d^2z}{dx_i dx_1} dx_1 + \frac{d^2z}{dx_i dx_2} dx_2 \dots + \frac{d^2z}{dx_i dx_n} dx_n \dots \dots (43).$$

Substituting this value in (42), we shall be permitted, in consequence of the independence of the differentials  $dx_1, dx_2, \dots, dx_n$ , to equate their respective coefficients to 0.

It is easy to see that the coefficient of  $dx_r$  will be

$$\frac{d\Phi}{dx_r} + p_r \frac{d\Phi}{dz} + \sum_i \frac{d\Phi}{dp_i} \frac{d^2z}{dx_i dx_r}.$$

Equating this to 0, we have, on transposition,

$$-\left(\frac{d\Phi}{dx_r} + p_r \frac{d\Phi}{dz}\right) = \sum_i \frac{d^2z}{dx_i dx_r} \frac{d\Phi}{dp_i}.$$

Hence, changing  $i$  into  $r$  and  $r$  into  $i$ ,

$$-\left(\frac{d\Phi}{dx_i} + p_i \frac{d\Phi}{dz}\right) = \sum_r \frac{d^2z}{dx_r dx_i} \frac{d\Phi}{dp_r} \dots \dots \dots (44).$$

Now comparing this with (43), and observing that

$$\frac{d^2z}{dx_i dx_r} = \frac{d^2z}{dx_r dx_i},$$

we see that the systems of differentials represented by  $dp_i$  and  $dx_r$  respectively are connected by the same relations as the systems of functions represented by

$$-\left(\frac{d\Phi}{dx_i} + p_i \frac{d\Phi}{dz}\right) \text{ and } \frac{d\Phi}{dp_r} \text{ respectively.}$$

Hence, by the reasoning of the previous example, it is permitted to substitute in (41), for the differentials, the corresponding functions, viz.  $-\left(\frac{d\Phi}{dx_i} + p_i \frac{d\Phi}{dz}\right)$  for  $dp_i$ ; and  $\frac{d\Phi}{dp_i}$  for  $dx_i$ . We thus find

$$\sum_i \left\{ \left( \frac{dF}{dx_i} + p_i \frac{dF}{dz} \right) \frac{d\Phi}{dp_i} - \frac{dF}{dp_i} \left( \frac{d\Phi}{dx_i} + p_i \frac{d\Phi}{dz} \right) \right\} = 0 \dots \dots (45),$$

the summation extending from  $i=1$  to  $i=n$ . This is the relation sought, and it is seen to be symmetrical with respect to  $F$  and  $\Phi$ . When  $F$  is given, it becomes a linear partial differential equation for determining  $\Phi$ . From its auxiliary system of ordinary differential equations it suffices to obtain  $n-1$  integrals,

$$\Phi_1 = a_1, \quad \Phi_2 = a_2, \dots \Phi_{n-1} = a_{n-1} \dots \dots \dots (46),$$

such as, in conjunction with the given equation, will enable us to determine  $p_1, p_2, \dots p_n$  in terms of the original variables; then integrating (39), we shall obtain the complete primitive in the form

$$f(x_1, x_2, \dots x_n, z, a_1, a_2, \dots a_n) = 0 \dots \dots \dots (47).$$

All other forms of solution are hence deducible by regarding  $a_1, a_2, \dots a_n$  as parameters varying, independently or in subjection to connecting relations, but so as to leave unaffected the *forms* of  $p_1, p_2, \dots p_n$ .

It is proper to observe that the given equation  $F=0$  is itself included among the particular integrals of (45). In fact  $F$  is one of the forms of  $\Phi$  which make  $\Phi=a$  a solution, as will be found on trial. The given equation is therefore a particular integral. And therefore the  $n-1$  integrals of the system (46) must be independent of it in order to render the determination of  $p_1, p_2, \dots p_n$  possible.

The equation (45) may be expressed as follows:

$$\sum_i \left( \frac{dF}{dx_i} \frac{d\Phi}{dp_i} - \frac{dF}{dp_i} \frac{d\Phi}{dx_i} \right) + \frac{dF}{dz} \sum_i p_i \frac{d\Phi}{dp_i} - \frac{d\Phi}{dz} \sum_i p_i \frac{dF}{dp_i} = 0.$$

And under this elegant form, obtained however by a more complex analysis, the solution is presented by Brioschi (*Torrolini*, Tom. VI. p. 426, *Intorno ad una proprietà delle equazioni alle derivate parziali del primo ordine*).

The problem of the integration of partial differential equations of the first order, irrespectively of the number of the variables, appears to have been first solved by Pfaff, but the

most complete discussion of it will be found in a memoir by Cauchy (*Exercices d'Analyse*, Tom. II. p. 238. *Sur l'intégration des équations aux dérivées partielles du premier ordre*), in which the determination of the arbitrary functions of the general primitive so as to satisfy given initial conditions is fully considered. The connexion of the subject with Theoretical Dynamics was first established by the researches of Sir W. Hamilton and Jacobi. The truth, illustrated above, that the solution of a partial differential equation of the first order is reducible to that of a system of ordinary differential equations, and the truth that the solutions of certain systems of differential equations (including that of dynamics) may be reduced to the discovery of a single function defined by a partial differential equation, are correlative. The researches above referred to, together with those of Liouville, Bertrand, and Bour, founded partly upon their results and partly upon the allied discoveries of Lagrange and Poisson concerning the variation of the arbitrary constants in dynamical problems, contain the most important of recent additions to our speculative knowledge of Differential Equations. For this reason we have dwelt upon their history. Fuller information will be found in Mr Cayley's excellent Report on the recent Progress of Theoretical Dynamics. (*Report of British Association*, 1857.)

[In an Appendix to the first edition Professor Boole presented Art. 14 in the following form.]

Art. 14. The most important form of the problem of this Article is the following, and the reader is requested to substitute it for the one in the text, sufficient account not being there taken of the conditions among the constants.

Required a value of  $z$  as a function of  $x_1, x_2, \dots x_n$  which shall satisfy the partial differential equation

$$F(x_1, x_2, \dots x_n, z, p_1, p_2, \dots p_n) = 0 \dots \dots \dots (1),$$

and shall, when  $x_n = 0$ , assume a *given* form,

$$z = \phi(x_1, x_2, \dots x_{n-1}) \dots \dots \dots (2).$$

Representing the second member of (2) by  $\phi$ , and  $\frac{d\phi}{dx_1}$  by  $\phi_1$ , &c., we shall have, when  $x_n = 0$ ,

$$p_1 = \phi_1, \quad p_2 = \phi_2, \quad \dots \quad p_{n-1} = \phi_{n-1}, \dots \dots \dots (3),$$

for, in seeking the forms which  $\frac{dz}{dx_1}, \frac{dz}{dx_2}, \dots \frac{dz}{dx_{n-1}}$  assume when  $x_n = 0$ , we are permitted to make  $x_n = 0$  in the general value of  $z$  before differentiating.

Now the auxiliary system of the linear equation, (45) in the text, yields  $2n$  integrals connecting  $x_1, \dots x_n, z, p_1, \dots p_n$  with  $2n$  arbitrary constants. But since one of the integrals is  $F=c$ , and since to make this agree with (1) we must have  $c=0$ , the  $2n$  integrals will effectively contain  $2n-1$  arbitrary constants. This however being the number of the variables contained in (2), (3), namely of the variables  $x_1, \dots x_{n-1}, z, p_1, \dots p_{n-1}$ , we may express, and so replace, these arbitrary constants by initial values of the above variables corresponding to  $x_n = 0$ .

Let  $\xi_1, \dots \xi_{n-1}, \zeta, \pi_1, \dots \pi_{n-1}$  be the new constants in question; then, substituting these for the variables whose initial values they represent in the  $n$  equations (2), (3), we obtain  $n$  conditions connecting the above constants.

Thus we have finally  $3n$  equations, consisting of  $2n$  integrals with  $n$  equations of condition connecting the  $2n-1$  constants which those integrals contain. From these  $3n$  equations we can eliminate the above  $2n-1$  constants together with the  $n$  quantities  $p_1, p_2, \dots p_n$ . The result will be a final relation between  $z, x_1, x_2, \dots x_n$ , which will be the solution sought.

If we regard the function  $\phi(x_1, x_2, \dots x_{n-1})$  as arbitrary, the above solution will constitute a *general* primitive; but if we give to it a particular form involving  $n$  arbitrary constants, we shall obtain a *complete* primitive. (Cauchy, *Exercices*, Vol. II. p. 238.)

[Important additions on partial differential equations of the first order are given in the *Supplementary Volume*, Chapters XXV., XXVI., and XXVII.]

## EXERCISES.

1. How are equations, in which all the differential coefficients have reference to only one of the variables, solved?

$$2. \quad \frac{dz}{dx} = \frac{y}{\sqrt{(y^2 - x^2)}}.$$

$$3. \quad \frac{dz}{dx} = \frac{y}{x + z}.$$

4. The partial differential equation of the first order which results from a primitive of the form  $u = f(v)$ , where  $u$  and  $v$  are determinate functions of  $x, y, z$ , is necessarily linear. Prove this.

$$5. \quad ap + bq = 1.$$

$$6. \quad p + q = \frac{z}{a}.$$

$$7. \quad yp + xq = z.$$

$$8. \quad x^2p - xyq + y^2 = 0.$$

9. Integrate the equation of conical surfaces

$$(a - x)p + (b - y)q = c - z.$$

$$10. \quad xzp + yzq = xy.$$

$$11. \quad (y^2 + z^2 - x^2)p - 2xyq + 2xz = 0.$$

12. Required the equation of the surface which cuts at right angles all the spheres which pass through the origin of co-ordinates and have their centres in the axis of  $x$ .

It will be found that this leads to the partial differential equation of the last problem.

$$13. \quad z - xp - yq = a(x^2 + y^2 + z^2)^{\frac{1}{2}}.$$

14. Find the equation of the surface which cuts at right angles the system of ellipsoids represented by the equation

$$Ax^2 + By^2 + Cz^2 = D^2,$$

where  $D$  is the variable parameter. *Lacroix*, Tom. II. p. 678.

15. Find the equation of a surface which belongs at once to surfaces of revolution defined by the equation  $py - qx = 0$ , and to conical surfaces defined by the equation  $px + qy = z$ .

In problems like the above we must regard the equations as simultaneous, determine  $p$  and  $q$  as functions of  $x, y, z$ , and substitute their values in the equation  $dz = p dx + q dy$ , which will become integrable by a single equation if the problem is a possible one, but not otherwise.

$$16. \quad x \frac{dz}{dx} + y \frac{dz}{dy} + t \frac{dz}{dt} = az + \frac{xy}{t}.$$

17. Explain the distinction between a complete primitive and a general primitive of a partial differential equation of the first order.

18. Find the complete and the general primitive of

$$z = px + qy + pq.$$

19. Deduce a singular solution of the above.

$$20. \quad pq = 1.$$

$$21. \quad q = xp + p^2.$$

22. Shew from the form of its integral that  $q = f(p)$  belongs only to developable surfaces.

23. Deduce two complete primitives of

$$pq = px + qy.$$

24. Deduce two complete primitives of

$$\sqrt{p} + \sqrt{q} = 2x.$$

25. Given two general primitives of a partial differential equation of the first order, in the forms,

$$\text{1st. } z = F\{x, y, a, \phi(a)\}, \quad 0 = \frac{dF\{x, y, a, \phi(a)\}}{da},$$

$$\text{2nd. } z = \Phi\{x, y, c, \psi(c)\}, \quad 0 = \frac{d\Phi\{x, y, c, \psi(c)\}}{dc},$$

shew that the dependence of the functions  $\psi(c)$  and  $\phi(a)$ , when the two primitives lead to the same particular integral, may be determined by the following rule. Eliminate  $x$  and  $y$  from any four independent equations of the system

$$F = \Phi, \quad \frac{dF}{dx} = \frac{d\Phi}{dx}, \quad \frac{dF}{dy} = \frac{d\Phi}{dy}, \quad \frac{dF}{da} = 0, \quad \frac{d\Phi}{dc} = 0.$$

The two resulting equations will involve the relation required, and when the form of  $\phi(a)$  is given, the elimination of  $a$  from both will give a differential equation for determining the form of  $\psi(c)$ .

26. The equation  $z = pq$  has two general primitives,

$$\text{1st. } z = (y + a)\{x + \phi(a)\}, \quad 0 = \frac{d}{da} [(y + a)\{x + \phi(a)\}],$$

$$\text{2nd. } 4z = \{cx + \frac{y}{c} + \psi(c)\}^2, \quad 0 = \frac{d}{dc} \{cx + \frac{y}{c} + \psi(c)\}^2;$$

shew hence that the relation between  $\phi(a)$  and  $\psi(c)$  is expressed by the equations

$$\phi'(a) + \frac{1}{c^2} = 0, \quad c\psi(c) - c^2\psi'(c) = 2a.$$

[An interesting problem involving partial differential equations of the first order is discussed in the *Supplementary Volume*, Chapter XXXIII.]

## CHAPTER XV.

### PARTIAL DIFFERENTIAL EQUATIONS OF THE SECOND ORDER.

1. THE general form of a partial differential equation of the second order is

$$F(x, y, z, p, q, r, s, t) = 0 \dots\dots\dots(1),$$

where

$$p = \frac{dz}{dx}, \quad q = \frac{dz}{dy}, \quad r = \frac{d^2z}{dx^2}, \quad s = \frac{d^2z}{dxdy}, \quad t = \frac{d^2z}{dy^2}.$$

It is only in particular cases that the equation admits of integration, and the most important is that in which the differential coefficients of the second order present themselves only in the first degree; the equation thus assuming the form

$$Rr + Ss + Tt = V \dots\dots\dots(2),$$

in which  $R, S, T$  and  $V$  are functions of  $x, y, z, p$  and  $q$ . This equation we propose to consider. The most usual method of solution, due to Monge, consists in a certain procedure for discovering either one or two first integrals of the form

$$u = f(v) \dots\dots\dots(3),$$

$u$  and  $v$  being determinate functions of  $x, y, z, p, q$ , and  $f$  an arbitrary functional symbol. From these first integrals, singly or in combination, the second integral involving two arbitrary functions is obtained by a subsequent integration.

An important remark must here be made. Monge's method involves the assumption that the equation (2) admits of a first integral of the form (3). Now this is not always the case. There exist primitive equations, involving two arbitrary functions, from which by proceeding to a second differentiation both functions may be eliminated and an equation of the form (2) obtained, but from which it is impossible to eliminate

one function only so as to lead to an intermediate equation of the form (3). Especially this happens if the primitive involve an arbitrary function and its derived function together. Thus the primitive

$$z = \phi(y+x) + \psi(y-x) - x\{\phi'(y+x) - \psi'(y-x)\} \dots (4),$$

leads to the partial differential equation of the second order

$$r - t = \frac{2p}{x} \dots \dots \dots (5),$$

but not through an intermediate equation of the form (3).

It is necessary therefore not only to explain Monge's method, but also to give some account of methods to be adopted when it fails.

[Part of the present Chapter is treated on a larger scale in the *Supplementary Volume*, Chapters XXVIII. and XXIX.]

2. It is not only not true that the equation (2) has necessarily a first integral of the form (3), but neither is the converse proposition true. We propose therefore, 1st, to inquire under what conditions an equation of the first order of the form (3) does lead to an equation of the second order of the form (2); 2ndly, to establish upon the results of this direct inquiry the inverse method of solution. And this procedure, though somewhat longer than that usually followed, is more simple, because exact and thorough.

PROP. 1. *A partial differential equation of the first order of the form  $u = f(v)$  can only lead to a partial differential equation of the second order of the form*

$$Rr + Ss + Tt = V \dots \dots \dots (6),$$

*when  $u$  and  $v$  are so related as to satisfy identically the condition*

$$\frac{du}{dp} \frac{dv}{dq} - \frac{du}{dq} \frac{dv}{dp} = 0 \dots \dots \dots (7).$$

For, differentiating the equation  $u = f(v)$  with respect to  $x$ , and observing that  $\frac{dz}{dx} = p$ ,  $\frac{dp}{dx} = r$ ,  $\frac{dq}{dx} = s$ , we have

$$\frac{du}{dx} + p \frac{du}{dz} + r \frac{du}{dp} + s \frac{du}{dq} = f'(v) \left( \frac{dv}{dx} + p \frac{dv}{dz} + r \frac{dv}{dp} + s \frac{dv}{dq} \right).$$

In like manner differentiating  $u = f(v)$  with respect to  $y$ , we have

$$\frac{du}{dy} + q \frac{du}{dz} + s \frac{du}{dp} + t \frac{du}{dq} = f'(v) \left( \frac{dv}{dy} + q \frac{dv}{dz} + s \frac{dv}{dp} + t \frac{dv}{dq} \right).$$

Eliminating  $f'(v)$  there results

$$\begin{aligned} & \left( \frac{du}{dx} + p \frac{du}{dz} + r \frac{du}{dp} + s \frac{du}{dq} \right) \left( \frac{dv}{dy} + q \frac{dv}{dz} + s \frac{dv}{dp} + t \frac{dv}{dq} \right) \\ & - \left( \frac{dv}{dx} + p \frac{dv}{dz} + r \frac{dv}{dp} + s \frac{dv}{dq} \right) \left( \frac{du}{dy} + q \frac{du}{dz} + s \frac{du}{dp} + t \frac{du}{dq} \right) = 0 \dots (8). \end{aligned}$$

On reduction it will be found that the only terms involving  $r$ ,  $s$ , and  $t$  in a degree higher than the first will be those which contain  $rt$  and  $s^2$ . The equation will in fact assume the form

$$Rr + Ss + Tt + U(rt - s^2) = V \dots \dots \dots (9),$$

in which  $U = \frac{du}{dp} \frac{dv}{dq} - \frac{du}{dq} \frac{dv}{dp}$ . The forms of the other coefficients it is unnecessary to examine.

Now this equation assumes the form (6) when the condition (7) is satisfied—and then only.

3. The proposition might also be proved in the following manner. Since  $u = f(v)$  we have  $du = f'(v) dv$ , an equation which, since  $f(v)$  is arbitrary, involves the two equations  $du = 0$ ,  $dv = 0$ . Hence

$$\left. \begin{aligned} \frac{du}{dx} dx + \frac{du}{dy} dy + \frac{du}{dz} dz + \frac{du}{dp} dp + \frac{du}{dq} dq &= 0 \\ \frac{dv}{dx} dx + \frac{dv}{dy} dy + \frac{dv}{dz} dz + \frac{dv}{dp} dp + \frac{dv}{dq} dq &= 0 \end{aligned} \right\} \dots (10).$$

But  $dz = p dx + q dy$ ,  $dp = r dx + s dy$ ,  $dq = s dx + t dy$ .

Whence on substitution

$$\left(\frac{du}{dx} + p \frac{du}{dz} + r \frac{du}{dp} + s \frac{du}{dq}\right) dx + \left(\frac{du}{dy} + q \frac{du}{dz} + s \frac{du}{dp} + t \frac{du}{dq}\right) dy = 0.$$

$$\left(\frac{dv}{dx} + p \frac{dv}{dz} + r \frac{dv}{dp} + s \frac{dv}{dq}\right) dx + \left(\frac{dv}{dy} + q \frac{dv}{dz} + s \frac{dv}{dp} + t \frac{dv}{dq}\right) dy = 0.$$

Whence eliminating  $dx$  and  $dy$ , we have the same result as before.

4. A consequence, which, though not affecting the present inquiry, is important, may here be noted. It is that it would be in vain to seek a first integral of the form  $u = f(v)$  for any partial differential equation of the second order which is not of the form (9).

PROP. 2. To deduce when possible a first integral, of the form  $u = f(v)$ , for the partial differential equation (6).

By the last proposition  $u$  and  $v$  must satisfy the condition (7), which is expressible in the form,

$$\frac{du}{dq} \div \frac{du}{dp} = \frac{dv}{dq} \div \frac{dv}{dp} \dots\dots\dots(11).$$

Hence, if we represent each member of this equation by  $m$ , we have

$$\frac{du}{dq} = m \frac{du}{dp}, \quad \frac{dv}{dq} = m \frac{dv}{dp} \dots\dots\dots(12).$$

Substituting these values in (10), we have

$$\left. \begin{aligned} \frac{du}{dx} dx + \frac{du}{dy} dy + \frac{du}{dz} dz + \frac{du}{dp} (dp + m dq) &= 0 \\ \frac{dv}{dx} dx + \frac{dv}{dy} dy + \frac{dv}{dz} dz + \frac{dv}{dp} (dp + m dq) &= 0 \end{aligned} \right\} \dots\dots(13);$$

and we are to remember that this system, being equivalent to  $du = 0$ ,  $dv = 0$  modified by the condition (7), can only have an integral system of the form,

$$u = a, \quad v = b \dots\dots\dots(14),$$

$a$  and  $b$  being arbitrary constants, and  $u$  and  $v$  connected by the condition (11).

Making  $dz = p dx + q dy$  in (13), we have

$$\left. \begin{aligned} \left( \frac{du}{dx} + p \frac{du}{dz} \right) dx + \left( \frac{du}{dy} + q \frac{du}{dz} \right) dy + \frac{du}{dp} (dp + m dq) &= 0 \\ \left( \frac{dv}{dx} + p \frac{dv}{dz} \right) dx + \left( \frac{dv}{dy} + q \frac{dv}{dz} \right) dy + \frac{dv}{dp} (dp + m dq) &= 0 \end{aligned} \right\} \dots (15).$$

From these and from the equations

$$dp = r dx + s dy, \quad dq = s dx + t dy \dots\dots\dots (16),$$

if we eliminate the differentials  $dx$ ,  $dy$ ,  $dp$ ,  $dq$ , we shall necessarily obtain a result of the form (6). For in thus doing we only repeat the process of Art. 3, with the added condition (7).

To effect this elimination, we have from (16),

$$dp + m dq = (r + ms) dx + (s + mt) dy;$$

$$\text{or,} \quad r dx + s (dy + m dx) + t m dy = dp + m dq \dots\dots\dots (17).$$

Now the system (15) enables us to determine the ratios of  $dy$  and  $dp + m dq$  to  $dx$ , and these ratios substituted in (17), reduce it to the form (6).

But in order that it may be, not only of the form (6), but actually equivalent to (6), it is necessary and sufficient that we have

$$\frac{dx}{R} = \frac{dy + m dx}{S} = \frac{m dy}{T} = \frac{dp + m dq}{V} \dots\dots\dots (18).$$

This system of relations among the differentials must thus include the equations (15). The same system (18), together with the equation  $dz = p dx + q dy$ , must therefore include the system (13). It must therefore in its final integral system include the equations  $u = a$ ,  $v = b$  with their implied condition,

We conclude then, that if the equation  $Rr + Ss + Tt = V$ , result from an equation of the first order of the form  $u = f(v)$ , the system (18), together with the equation,

$$dz = pdx + qdy \dots\dots\dots (19),$$

must admit of an integral system determining  $u$  and  $v$  in equations of the form  $u = a$ ,  $v = b$ .

To eliminate  $m$  from (18) we have, on determining its value from the first and third members, substituting it in the second and fourth, and reducing,

$$Rdy^2 - Sdxdy + Tdx^2 = 0 \dots\dots\dots (20),$$

$$Rdpdy + Tdqdx - Vdxdy = 0 \dots\dots\dots (21),$$

and these, with (19), make three ordinary differential equations among the five variables  $x, y, z, p, q$ . But among five variables there ought to exist four ordinary differential equations in order to render the final relations determinate. And this confirms what was said in Art. 1, of the hypothetical character of Monge's method. It is only when the proposed equation originates in an equation of the form  $u = f(v)$ , that the above system admits of two integrals of the form,

$$u = a, \quad v = b.$$

As (20) is of the second degree it will, unless it is a complete square, be resolvable into two equations of the first degree, and either of these in conjunction with (21) and (19) may lead to a final integral system determining  $u$  and  $v$ . It follows that when the given equation admits of a first integral at all, it will admit of two such—excepting the case in which (20) is a complete square.

5. As yet no account has been taken of the quantity  $m$ . The mode in which it is involved in the equation (18), leads however to a remarkable consequence developed in the following Proposition.

PROP. If by the last proposition we obtain two first integrals of the form

$$u_1 = f(v_1), \quad u_2 = \phi(v_2) \dots\dots\dots (22),$$

and if, regarding these as simultaneous, we determine  $p$  and  $q$  as functions of  $x, y, z$ , those values will be such as to render the equation  $dz = p dx + q dy$  integrable, and thus to lead to the second or final integral.

For simplicity, we shall represent  $u_1 - f(v_1)$  by  $F$ , and  $u_2 - \phi(v_2)$  by  $\Phi$ . Thus the supposed first integrals are simply

$$F = 0, \quad \Phi = 0 \dots\dots\dots (23).$$

Now reverting to the system (18), and representing the ratio  $dy : dx$  by  $n$ , its first two equations assume the form,

$$\frac{1}{R} = \frac{n + m}{S} = \frac{nm}{T},$$

and shew that  $m$  and  $n$  are the two roots of the equation

$$R\mu^2 - S\mu + T = 0.$$

Hence, the value of the ratio  $dy : dx$  corresponding to one of the first integrals (23), is the same as the value of  $m$  corresponding to the other.

Now for the value of  $m$  corresponding to the integral  $F = 0$ , we have by definition,

$$\begin{aligned} m &= \frac{\frac{du_1}{dq}}{\frac{du_1}{dp}} = \frac{\frac{dv_1}{dq}}{\frac{dv_1}{dp}} \\ &= \frac{\frac{du_1}{dq} - f'(v) \frac{dv_1}{dq}}{\frac{du_1}{dp} - f'(v) \frac{dv_1}{dp}} \\ &= \frac{\frac{dF}{dq}}{\frac{dF}{dp}} \dots\dots\dots (24). \end{aligned}$$

Again, seeking the value of the ratio  $dy : dx$ , corresponding to the integral  $\Phi = 0$ , we have

$$\left(\frac{d\Phi}{dx} + \frac{d\Phi}{dz} p + \frac{d\Phi}{dp} r + \frac{d\Phi}{dq} s\right) dx \\ + \left(\frac{d\Phi}{dy} + \frac{d\Phi}{dz} q + \frac{d\Phi}{dp} s + \frac{d\Phi}{dq} t\right) dy = 0.$$

Equating the value of  $dy : dx$  hence found to that of  $m$  given in (24), we have, on reduction,

$$\frac{dF}{dp} \frac{d\Phi}{dx} + \frac{dF}{dq} \frac{d\Phi}{dy} + \frac{dF}{dp} \frac{d\Phi}{dz} p + \frac{dF}{dq} \frac{d\Phi}{dz} q \\ + \frac{dF}{dp} \frac{d\Phi}{dp} r + \left(\frac{dF}{dp} \frac{d\Phi}{dq} + \frac{dF}{dq} \frac{d\Phi}{dp}\right) s + \frac{dF}{dq} \frac{d\Phi}{dq} t = 0 \dots (25).$$

In like manner equating the values of  $m$  corresponding to the integral  $\Phi = 0$ , and of  $dy : dx$  corresponding to the integral  $F = 0$ , we have

$$\frac{dF}{dx} \frac{d\Phi}{dp} + \frac{dF}{dy} \frac{d\Phi}{dq} + \frac{dF}{dz} \frac{d\Phi}{dp} p + \frac{dF}{dz} \frac{d\Phi}{dq} q \\ + \frac{dF}{dp} \frac{d\Phi}{dp} r + \left(\frac{dF}{dq} \frac{d\Phi}{dp} + \frac{dF}{dp} \frac{d\Phi}{dq}\right) s + \frac{dF}{dq} \frac{d\Phi}{dq} t = 0 \dots (26).$$

Subtracting (25) from (26), there results

$$\frac{dF}{dx} \frac{d\Phi}{dp} - \frac{dF}{dp} \frac{d\Phi}{dx} + \frac{dF}{dy} \frac{d\Phi}{dq} - \frac{dF}{dq} \frac{d\Phi}{dy} \\ + \left(\frac{dF}{dz} \frac{d\Phi}{dp} - \frac{dF}{dp} \frac{d\Phi}{dz}\right) p + \left(\frac{dF}{dz} \frac{d\Phi}{dq} - \frac{dF}{dq} \frac{d\Phi}{dz}\right) q = 0 \dots (27).$$

Now this is identical with the equation (37), Chap. XIV. Art. 13, expressing the very condition which must be fulfilled in order that the values of  $p$  and  $q$  given by  $F = 0$ ,  $\Phi = 0$ , may render the equation  $dz = p dx + q dy$  an exact differential. Hence the proposition is established.

It is interesting to observe that the two first integrals stand in a certain conjugate relation. Each of them satisfies that partial differential equation of the first order and degree which

we should have to construct in attempting, by the process of Charpit, to integrate the other. Hence also, although the knowledge of both is desirable, that of either is sufficient to enable us to proceed by integration to the final solution.

6. The statement of Monge's method, as derived from the above investigation, is contained in the following Rule.

RULE. The equation being  $Rr + Ss + Tt = V$ , form first, the equation

$$Rdy^2 - Sdx dy + Tdx^2 = 0 \dots\dots\dots(28),$$

and resolve it, supposing the first member not a complete square, into two equations of the form

$$dy - m_1 dx = 0, \quad dy - m_2 dx = 0 \dots\dots\dots(29).$$

From the first of these, and from the equation

$$Rdp dy + Tdq dx - Vdx dy = 0 \dots\dots\dots(30),$$

combined if needful with the equation  $dz = p dx + q dy$ , seek to obtain two integrals  $u_1 = \alpha$ ,  $v_1 = b$ . Proceeding in the same way with the second equation of (29), seek two other integrals  $u_2 = \alpha$ ,  $v_2 = \beta$ , then the two first integrals of the proposed equation will be

$$u_1 = f_1(v_1), \quad u_2 = f_2(v_2) \dots\dots\dots(31).$$

To deduce the second integral, we must either integrate one of these, or, determining from the two  $p$  and  $q$  in terms of  $x$ ,  $y$ , and  $z$ , substitute those values in the equation

$$dz = p dx + q dy,$$

which will then satisfy the condition of integrability. Its solution will give the second integral sought.

If the values of  $m_1$  and  $m_2$  are equal, only one first integral will be obtained, and the final solution must be sought by its integration.

When it is not possible so to combine the auxiliary equations as to obtain two auxiliary integrals  $u = \alpha$ ,  $v = b$ , no first integral of the proposed equation exists, and some other process of solution must be sought.

We may observe that the determination of  $p$  and  $q$  from the two first integrals is facilitated by the fact that  $u$  and  $v$  satisfy the condition (7). Interpreted by Chap. II. Art. 1, that condition implies that  $p$  and  $q$  enter, in some single definite combination, in both  $u$  and  $v$ .

Ex. 1. Given  $\frac{d^2z}{dx^2} - a^2 \frac{d^2z}{dy^2} = 0$ .

Here  $R = 1$ ,  $S = 0$ ,  $T = -a^2$ ,  $V = 0$ . Hence we have by (28) and (30),

$$dy^2 - a^2 dx^2 = 0, \quad dpdy - a^2 dqdx = 0 \dots\dots(a).$$

The former of these is resolvable into the two equations

$$dy + adx = 0, \quad dy - adx = 0 \dots\dots\dots(b),$$

of which the first gives  $y + ax = c$ , and at the same time reduces the second equation of (a) to the form  $dp + adq = 0$ , of which the integral is  $p + aq = C$ . Thus a first integral of the given equation is

$$p + aq = \phi(y + ax) \dots\dots\dots(c).$$

Proceeding in like manner with the second equation of (b), we find as another first integral

$$p - aq = \psi(y - ax) \dots\dots\dots(d).$$

From these two equations determining  $p$  and  $q$ , the equation  $dz = pdx + qdy$  becomes

$$dz = \frac{\phi(y + ax) + \psi(y - ax)}{2} dx + \frac{\phi(y + ax) - \psi(y - ax)}{2a} dy.$$

Or

$$dz = \frac{\phi(y + ax)(dy + adx) - \psi(y - ax)(dy - adx)}{2a}.$$

Hence if  $\frac{1}{2a} \int \phi(t) dt = \phi_1(t)$  and  $-\frac{1}{2a} \int \psi(t) dt = \psi_1(t)$ ,

we have

$$z = \phi_1(y + ax) + \psi_1(y - ax).$$

Here  $\phi_1$ ,  $\psi_1$  are arbitrary functions since  $\phi$  and  $\psi$  are such.

It is seen that, in each of the first integrals, the condition (7) is satisfied, and assuming

$$p + aq - \phi(y + ax) = F, \quad p - aq - \psi(y - ax) = \Phi,$$

it is easy to verify the condition (27).

Ex. 2. Given  $r + as + bt = 0$ .

Proceeding as before, we find

$$p + nq = \phi(y - mx), \quad p + mq = \psi(y - nx),$$

as the two first integrals of the proposed,  $m$  and  $n$  being the roots of the equation  $t^2 - at + b = 0$ . Hence, determining  $p$  and  $q$ , substituting in the equation  $dz = pdx + qdy$ , integrating and reducing we have

$$z = \phi_1(y - mx) + \psi_1(y - nx).$$

But when  $m$  and  $n$  are equal we have only one first integral, viz.

$$p + mq = \phi(y - mx).$$

Treating this by Lagrange's process, we have the auxiliary system

$$dx = \frac{dy}{m} = \frac{dz}{\phi(y - mx)}.$$

From the first two members we find  $y - mx = c$ . This enables us to reduce the equation of the first and third to the form

$$dx = \frac{dz}{\phi(c)},$$

whence

$$z = x\phi(c) + c'.$$

Therefore, restoring to  $c$  its value,

$$z - x\phi(y - mx) = c'.$$

Thus we have for the final integral

$$z - x\phi(y - mx) = \psi(y - mx).$$

Ex. 3. Given

$$(b + cq)^2 r - 2(b + cq)(a + cp)s + (a + cp)^2 t = 0.$$

Here the auxiliary equations are

$$(b + cq)^2 dy^2 + 2(b + cq)(a + cp) dy dx + (a + cp)^2 dx^2 = 0 \dots (a).$$

$$(b + cq)^2 dp dy + (a + cp)^2 dq dx = 0 \dots \dots \dots (b).$$

The first of these equations gives

$$(b + cq) dy + (a + cp) dx = 0 \dots \dots \dots (c),$$

which the equation  $dz = p dx + q dy$  reduces to the form

$$a dx + b dy + c dz = 0;$$

whence

$$ax + by + cz = \alpha \dots \dots \dots (d).$$

Again, eliminating  $dy$  and  $dx$  from (b) and (c), we have

$$(b + cq) dp - (a + cp) dq = 0,$$

whence, integrating,

$$\frac{a + cp}{b + cq} = \beta \dots \dots \dots (e).$$

Thus a first integral of the proposed equation is

$$\frac{a + cp}{b + cq} = \phi(ax + by + cz),$$

or

$$cp - c\phi(ax + by + cz)q = b\phi(ax + by + cz) - a;$$

and this must be integrated by Lagrange's process.

The auxiliary system is, on representing  $\phi(ax + by + cz)$  by  $\phi$ ,

$$\frac{dx}{c} = -\frac{dy}{c\phi} = \frac{dz}{b\phi - a}.$$

From these we find  $adx + bdy + cdz = 0$ , whence

$$ax + by + cz = C,$$

and thus

$$\phi(ax + by + cz) = \phi(C).$$

Hence substituting  $dy = -\phi(C) dx$ ,

whence  $y + \phi(C) x = C'$ ,

or  $y + x\phi(ax + by + cz) = C'$ .

Thus the final integral is

$$y + x\phi(ax + by + cz) = \psi(ax + by + cz).$$

This solution may also be expressed in the form

$$z = x\phi_1(ax + by + cz) + y\psi_1(ax + by + cz),$$

in which it is in fact presented by Monge, (*Application de l'Analyse à la Géométrie*, Liouville's edition, p. 79). The equation solved is that of surfaces formed by the motion of a straight line which is always parallel to a given plane, and always passes through two given curves.

7. In the above examples  $V$  is equal to 0, and this always facilitates the application of Monge's method. The following is an example in which  $V$  is not equal to 0.

Ex. 4. Given  $r - t = -\frac{4p}{x + y}$ .

The auxiliary equations being

$$dy^2 - dx^2 = 0, \quad dpdy - dqdx + \frac{4p}{x + y} dx dy = 0,$$

one of the systems hence derived is

$$dy - dx = 0, \quad dp - dq + \frac{4p}{x + y} dx = 0.$$

There is also another system, but it is not integrable in the form  $u = a, v = b$ .

From the first of the above equations we get

$$y - x = a, \quad dp - dq + \frac{4pdx}{2y - a} = 0,$$

the latter of which may, since  $dz = pdx + qdx$ , be reduced to the form

$$d(2y - a)(p - q) + 2dz = 0,$$

whence  $(2y - a)(p - q) + 2z = b,$

or, replacing  $a$  by  $y - x,$

$$(x + y)(p - q) + 2z = b.$$

Hence a first integral of the proposed equation will be

$$(x + y)(p - q) + 2z = f(y - x).$$

Now this being linear, we have, by Lagrange's method, the auxiliary system

$$\frac{dx}{x + y} = \frac{-dy}{x + y} = \frac{dz}{f(y - x) - 2z}.$$

The equation of the first two members gives  $y + x = a,$  and this reduces the equation of the second and third to the form

$$\frac{-dy}{a} = \frac{dz}{f(2y - a) - 2z},$$

or 
$$\frac{dz}{dy} - \frac{2z}{a} = -\frac{f(2y - a)}{a},$$

whence 
$$z = \frac{-e^{\frac{2y}{a}}}{a} \int e^{-\frac{2y}{a}} f(2y - a) dy + b.$$

The final integral will therefore be found by substituting in the above, after integration,  $y + x$  for  $a,$  and  $F(y + x)$  for  $b.$

8. Monge's method fails in so many cases, owing to the non-existence of a first integral of the assumed form  $u = f(v),$  that it becomes important to inquire how its defects may be supplied. And various methods, all of limited generality, have been discovered. Thus Laplace has developed a method applicable to all equations of the form

$$Rr + Ss + Tt + Pp + Qq + Zz = U;$$

$R, S, T, P, Q, Z,$  and  $U$  being functions of  $x$  and  $y$  only,—which consists in a series of transformations, each of which has the effect of reducing the equation to the form

$$s + Pp + Qq + Zz = U,$$

$P$ ,  $Q$ ,  $Z$  and  $U$  being functions of  $x$  and  $y$ , to which each transformation gives new forms. It may be that among these successive forms, some one will be found which will admit of resolution into two linear equations of the first order. But there are probably no instances in which this method has been applied in which the solution may not be effected with far greater elegance, and with far greater simplicity, by the symbolical methods of the following Chapters. And even Laplace's method is better exhibited in a symbolical form. The subject will be resumed. See Chap. XVII. Art. 14.

The following sections contain miscellaneous but important additions.

### *Miscellaneous Theorems.*

9. Poisson has shewn how to deduce a particular integral of any partial differential equation of the form

$$P = (rt - s^2)^n Q \dots \dots \dots (45),$$

where  $P$  is a function of  $p, q, r, s, t$ , homogeneous with respect to the three last,  $n$  a positive index, and  $Q$  any function of  $x, y, z$ , and the differential coefficients of  $z$  of any order, which does not become infinite when  $rt - s^2 = 0$ .

Assuming  $q = \phi(p)$ , we have

$$s = \phi'(p) r, \quad t = \phi'(p) s = \{\phi'(p)\}^2 r \dots \dots \dots (46),$$

values which make  $rt - s^2 = 0$ . Hence, substituting in (45), the second member vanishes, while in the first, which is homogeneous with respect to  $r, s, t$ , some power of  $r$  only will remain as a common factor. Dividing by that factor, we shall have an equation involving only  $p, \phi(p)$ , and  $\phi'(p)$ , i.e.  $p, q$ , and  $\frac{dq}{dp}$ . Integrating this as an ordinary differential equation we obtain a relation between  $p, q$  and an arbitrary constant; and this, integrated as a partial differential equation of the first order, gives the solution in question.

Ex. Given  $r^2 - t^2 = rt - s^2$ .

Proceeding as above, we find  $1 - \{\phi'(p)\}^4 = 0$  ;  
therefore  $1 - \{\phi'(p)\}^2 = 0$ ,

whence  $\frac{dq}{dp} = \pm 1$ ,  $q = \pm p + c$  ;

therefore  $z - cy = \phi(y \pm x)$ ,  
a particular integral.

The above method is applicable to all equations of the second order which are homogeneous with respect to  $r, s, t$ , for then we have only to suppose  $Q = 0$ .

10. There exists in partial differential equations a remarkable duality, in virtue of which each equation stands connected with some other equation of the same order by relations of a perfectly reciprocal character. As respects equations of the first order the principle may be thus stated.

*Suppose that in the given equation*

$$\phi(x, y, z, p, q) = 0 \dots\dots\dots(47)$$

*we interchange  $x$  and  $p$ ,  $y$  and  $q$ , and change  $z$  into  $px + qy - z$ , giving*

$$\phi(p, q, px + qy - z, x, y) = 0 \dots\dots\dots(48) ;$$

*then, if either of these equations can be integrated in the form  $z = \psi(x, y)$ , the solution of the other will be found by eliminating  $X$  and  $Y$  between the equations*

$$x = \frac{d\psi(X, Y)}{dX}, \quad y = \frac{d\psi(X, Y)}{dY},$$

$$z = Xx + Yy - \psi(X, Y) \dots\dots\dots(49).$$

For, since  $dz = pdx + qdy$ , we have

$$z = px + qy - \int (xdp + ydq) \dots\dots\dots(50).$$

Hence  $xdp + ydq$  is an exact differential. Represent it by  $dZ$ , and assume  $Z$  for dependent variable. Assume also two new independent variables  $X$  and  $Y$ , connected with the former ones by the relations  $X = p$ ,  $Y = q$ . Then

$$dZ = xdp + ydq = xdX + ydY.$$

Hence 
$$\frac{dZ}{dX} = x, \quad \frac{dZ}{dY} = y,$$

$$Z = \int (x dp + y dq) = px + qy - z \text{ by (50) ;}$$

therefore 
$$z = px + qy - Z = xX + yY - Z.$$

On examining the above equations we see that  $x, y, z$ , and  $X, Y, Z$  are reciprocally related. Writing, side by side, the equations which are conjugate to each other, we have

$$X = \frac{dz}{dx}, \quad x = \frac{dZ}{dX};$$

$$Y = \frac{dz}{dy}, \quad y = \frac{dZ}{dY};$$

$$Z = Xx + Yy - z, \quad z = xX + yY - Z.$$

We see too that the equations (49) which express one set of the relations suffice to convert any relation found by integration between  $X, Y, Z$ , where  $Z$  stands for  $\psi(X, Y)$ , into a corresponding relation between  $x, y, z$ .

Ex. Given  $z = pq$ .

Here the transformed equation is

$$px + qy - z = xy,$$

of which the integral is  $z = xy + xf\left(\frac{y}{x}\right)$ . Hence

$$\psi(X, Y) = XY + Xf\left(\frac{Y}{X}\right),$$

and we have to eliminate  $X, Y$ , between the equations

$$x = Y - \frac{Y}{X}f'\left(\frac{Y}{X}\right) + f\left(\frac{Y}{X}\right), \quad y = X + f''\left(\frac{Y}{X}\right),$$

$$z = XY.$$

Each particular form assigned to  $f$  gives a distinct particular integral. If we assume  $f\left(\frac{Y}{X}\right) = a\frac{Y}{X} + b$ , we find

$$x = Y + b, \quad y = X + a, \quad z = XY,$$

from which, eliminating  $X$  and  $Y$ , we have  $z = (x - b)(y - a)$ , and this is one form of the complete primitive assigned in Chap. XIV. Art. 7. We may observe that the elimination may be so effected as to lead to general primitives.

11. *In equations of the second order we should have, in addition to the above transformations, to change*

$$r \text{ into } \frac{t}{rt - s^2}, \quad s \text{ into } \frac{-s}{rt - s^2}, \quad t \text{ into } \frac{r}{rt - s^2} \dots\dots (51),$$

*in order to form the reciprocal equation. Then the second integral of either being found in the form  $z = \psi(x, y)$ , that of the other will be found as before by eliminating  $X$  and  $Y$  from (49). For since*

$$x = \frac{dZ}{dX}, \quad y = \frac{dZ}{dY};$$

therefore  $dx = R dX + S dY$ ,  $dy = S dX + T dY$ ,

whence  $dX = \frac{T dx - S dy}{RT - S^2}$ ,  $dY = \frac{-S dx + R dy}{RT - S^2}$ .

But  $X = p$ ,  $Y = q$ , therefore

$$dp = r dx + s dy = \frac{T dx - S dy}{RT - S^2},$$

$$dq = s dx + t dy = \frac{-S dx + R dy}{RT - S^2},$$

whence, equating coefficients,

$$r = \frac{T}{RT - S^2}, \quad s = \frac{-S}{RT - S^2}, \quad t = \frac{R}{RT - S^2}.$$

The extension of the theorem to higher orders involves no difficulty.

12. It is an immediate consequence of the above, that any equation of the form

$$\phi(p, q)r + \psi(p, q)s + \chi(p, q)t = 0 \dots\dots\dots(52)$$

can be reduced to an equation of the form

$$\chi(x, y)r - \psi(x, y)s + \phi(x, y)t = 0 \dots\dots\dots(53),$$

usually more convenient for solution. Legendre's solution of the equation

$$(1 + q^2)r - 2pq s + (1 + p^2)t = 0,$$

by the aid of the above transformation, will be found in *Lacroix* (Tom. II. p. 623).

The same transformation makes the solution of any equation of the form  $Rr + Ss + Tt = V(rt - s^2)$  dependent on that of an equation of the form

$$Rr + Ss + Tt = V,$$

but with different coefficients. The subject of these transformations has been most fully treated by Prof. De Morgan (*Cambridge Philosophical Transactions*, Vol. VIII. p. 606).

13. Legendre also shews how, by a transformation formally resembling the above, to integrate the equation

$$r = f(s, t).$$

Assuming  $s$  and  $t$  as independent variables, and  $v = sx + ty - q$  as dependent variable, the equation is reduced to the form

$$\frac{d^2 v}{dt^2} + S \frac{d^2 v}{ds dt} - T \frac{d^2 v}{ds^2} = 0 \dots\dots\dots(54),$$

where  $S$  and  $T$  are the values of  $\frac{dr}{ds}$  and  $\frac{dr}{dt}$  furnished by the given equation. *Lacroix*, Tom. II. p. 631.

## EXERCISES.

1. To what condition must  $u$  and  $v$  be subject, in order that  $u=f(v)$  may be a first integral of an equation of the form  $Rr + Ss + Tt = V$ ?

Integrate by Monge's method the following equations :

2.  $x^2r + 2xys + y^2t = 0$

3.  $q^2r - 2pqs + p^2t = 0.$

4. Integrate  $ps - qr = 0.$

5. Integrate by Monge's method the equation

$$q(1+q)r - (p+q+2pq)s + p(1+p)t = 0.$$

6. The solution of Ex. 3 may, by the law of reciprocity, be made to depend on that of Ex. 2.

7. Monge's method would not enable us to solve the equation  $r - t = \frac{2p}{x}.$

8. Deduce by Poisson's method a particular integral of

$$(1+q^2)r - 2pqs + (1+p^2)t = 0.$$

9. Shew that the equations

$$rt - s^2 = f(p, q), \text{ and } rt - s^2 = \{f(x, y)\}^{-1},$$

are connected by the law of reciprocity.

10. The solution of the equation  $r - t = \frac{4x}{p+q}(rt - s^2)$  may be derived from that of the equation  $r - t + \frac{4p}{x+y} = 0,$   
Art. 7, Ex. 4.

# CHAPTER XVI.

## SYMBOLICAL METHODS.

1. THE term symbolical is, by a restriction of its wider meaning, applied more peculiarly to those methods in Analysis in which operations, separated by a mental abstraction from the subjects upon which they are performed, are expressed by symbols in whose laws the laws of the operations themselves are represented.

Thus  $\frac{du}{dx}$  is written symbolically in the form  $\frac{d}{dx} u$ , the symbol  $\frac{d}{dx}$  denoting an operation of which  $u$  is the subject. In thus expressing an operation by a symbol, in studying the laws of that symbol, and in founding processes and methods upon those laws, we introduce no strange or novel principle of Language; for it is the very office of Language to express by symbols the procedure of Thought.

Thus also we may write

$$\frac{du}{dx} + au = \left( \frac{d}{dx} + a \right) u \dots\dots\dots(1),$$

$$\frac{d^2u}{dx^2} + a \frac{du}{dx} + bu = \left( \frac{d^2}{dx^2} + a \frac{d}{dx} + b \right) u \dots\dots\dots(2),$$

and so on. It will be observed that the symbol precedes the subject on which it operates.

Operations may be performed in succession. Thus

$$\left( \frac{d}{dx} + a \right) \left( \frac{d}{dx} + b \right) u$$

denotes that we first perform on the subject  $u$  the operation

denoted by  $\frac{d}{dx} + b$ , and then on the result effect the operation denoted by  $\frac{d}{dx} + a$ . Thus  $a$  and  $b$  being constant, we have

$$\begin{aligned} \left(\frac{d}{dx} + a\right) \left(\frac{d}{dx} + b\right) u &= \left(\frac{d}{dx} + a\right) \left(\frac{du}{dx} + bu\right) \\ &= \frac{d}{dx} \left(\frac{du}{dx} + bu\right) + a \left(\frac{du}{dx} + bu\right) \\ &= \frac{d^2u}{dx^2} + (a + b) \frac{du}{dx} + abu \dots\dots(3). \end{aligned}$$

When an operation is repeated, the number of times which it is understood to be performed is expressed by an index attached to the symbol of operation. Thus

$$\begin{aligned} \left(\frac{d}{dx} + a\right)^2 u &= \left(\frac{d}{dx} + a\right) \left(\frac{d}{dx} + a\right) u \\ &= \frac{d^2u}{dx^2} + 2a \frac{du}{dx} + a^2u \dots\dots\dots(4). \end{aligned}$$

If in the second member of (3), as in the first, we separate the symbols from their subject, we have

$$\left(\frac{d}{dx} + a\right) \left(\frac{d}{dx} + b\right) u = \left\{ \frac{d^2}{dx^2} + (a + b) \frac{d}{dx} + ab \right\} u \dots\dots(5).$$

Now the symbolic expressions for the equivalent operations performed upon  $u$  in the two members of this equation are in *formal* analogy with the algebraic equation

$$(m + a)(m + b)u = \{m^2 + (a + b)m + ab\}u,$$

and this is a particular illustration of a general theorem to the statement and demonstration of which we shall now proceed.

2. If we compare the symbolical expressions

$$\left(\frac{d}{dx} + a\right) \left(\frac{d}{dx} + b\right), \quad \frac{d^2}{dx^2} + (a + b) \frac{d}{dx} + ab \dots\dots\dots(6),$$

whose equivalence is stated in (5), we see that each involves  $\frac{d}{dx}$  together with constant quantities. Each might therefore, to borrow the language of analogy, be described as a function of  $\frac{d}{dx}$  and constant quantities, or more briefly as a function of  $\frac{d}{dx}$ , and expressed in the form  $f\left(\frac{d}{dx}\right)$ . Again, each expresses a system of operations in the performance of which the presence of the symbol  $\frac{d}{dx}$  only indicates *differentiation*, not integration. We may with propriety term any function of  $\frac{d}{dx}$  possessing this character a *direct* function of  $\frac{d}{dx}$ . The theorem in question is then the following.

**THEOREM.** Any direct function of  $\frac{d}{dx}$  and constant quantities may be transformed as if  $\frac{d}{dx}$  were itself a quantity.

In the first place it is evident that any direct function of the symbol  $\frac{d}{dx}$  according to the above definition is, in form, what we should term a rational and integral function of  $\frac{d}{dx}$ , were that symbol merely algebraic.

Now the laws, according to which algebraic symbols combine with each other in the composition of all rational and integral expressions, are the following, viz.

1st, the distributive, expressed by the equation

$$m(u + v) = mu + mv \dots\dots\dots(7),$$

2ndly, the commutative, expressed by the equation

$$ma = am \dots\dots\dots(8),$$

3rdly, the index law, expressed by the equation

$$m^a m^b = m^{a+b} \dots\dots\dots(9).$$

These determine, and alone determine, the forms, or, to speak more precisely, the permitted variety of form, of algebraic expressions of the above class.

But the symbol  $\frac{d}{dx}$ , when employed in combination with constant quantities to operate on subjects which are not constant, is subject to laws formally agreeing with the above. For we have

$$\frac{d}{dx}(u + v) = \frac{d}{dx}u + \frac{d}{dx}v \dots\dots\dots(10),$$

$$\frac{d}{dx}au = a \frac{d}{dx}u \dots\dots\dots(11),$$

$$\left(\frac{d}{dx}\right)^a \left(\frac{d}{dx}\right)^b u = \left(\frac{d}{dx}\right)^{a+b} u \dots\dots\dots(12),$$

the last of these, however, expressing, not any distinctive property of the operation  $\frac{d}{dx}$ , but only the fact that it is an operation capable of repetition. These laws, in like manner, determine the possible forms of symbolic expressions involving  $\frac{d}{dx}$  with constants, and representing direct systems of operations.

Hence the variety of form permitted in the one case is the same as that permitted in the other. In other words, the same transformations are valid.

Among the consequences of the above theorem the following may be noted.

1st, We can reduce any symbolical expression of the form  $\frac{d^n}{dx^n} + a_1 \frac{d^{n-1}}{dx^{n-1}} + a_2 \frac{d^{n-2}}{dx^{n-2}} \dots + a_n$ , in which  $a_1, a_2, \dots a_n$  are constants, to an equivalent expression of the form

$$\left(\frac{d}{dx} - m_1\right) \left(\frac{d}{dx} - m_2\right) \dots \left(\frac{d}{dx} - m_n\right),$$

where  $m_1, m_2, \dots m_n$  are the roots of the equation

$$m^n + a_1 m^{n-1} + a_2 m^{n-2} \dots + a_n = 0.$$

2ndly, The order, in which the component operations

$$\frac{d}{dx} - m_1, \quad \frac{d}{dx} - m_2, \dots \frac{d}{dx} - m_n$$

are written, is indifferent.

Ex. Thus  $\frac{d^2 u}{dx^2} - a^2 u = 0$  may be reduced to either of the forms

$$\left(\frac{d}{dx} + a\right)\left(\frac{d}{dx} - a\right)u = 0, \quad \left(\frac{d}{dx} - a\right)\left(\frac{d}{dx} + a\right)u = 0.$$

3rdly, The complex operation

$$\frac{d^n}{dx^n} + A_1 \frac{d^{n-1}}{dx^{n-1}} + A_2 \frac{d^{n-2}}{dx^{n-2}} \dots + A_n$$

is itself, like the elementary operation  $\left(\frac{d}{dx}\right)$ , distributive; i.e. representing that complex operation by  $f\left(\frac{d}{dx}\right)$ , we have

$$f\left(\frac{d}{dx}\right)(u + v) = f\left(\frac{d}{dx}\right)u + f\left(\frac{d}{dx}\right)v \dots\dots\dots(13).$$

This conclusion may be verified, by substituting for  $f\left(\frac{d}{dx}\right)$  the expression for which it stands, and performing the operations.

### *Inverse Forms.*

3. All that is said above relates to the performance of operations, definite in character, upon subjects supposed to be given. But an inverse problem is suggested, in which it is required to determine, not what will be the result of performing a certain operation upon a given subject, but upon what

subject a certain operation must be performed in order to lead to a given result. Thus, in the equation

$$\left(\frac{d}{dx} + a\right)u = v \dots\dots\dots(14),$$

if  $u$  be given, the performance of the operation  $\frac{d}{dx} + a$  determines  $v$ ; but if  $v$  be given, then the inquiry arises, what is that unknown subject  $u$ , the performance of the operation  $\frac{d}{dx} + a$  upon which will lead to the result  $v$ ?

As any procedure for determining  $u$  from  $v$  is inverse to the procedure by which  $v$  is determined from  $u$ , analogy suggests the notation

$$u = \left(\frac{d}{dx} + a\right)^{-1} v \dots\dots\dots(15),$$

$\left(\frac{d}{dx} + a\right)^{-1}$  representing the inverse procedure in question, but representing that procedure only in its inverse character, i.e. conveying no information as to how it is to be performed, but only telling us that it must be such, that if, having performed it on  $v$ , we perform on the result the operation  $\frac{d}{dx} + a$  to which it is inverse, we shall reproduce  $v$ . For, substituting in (14) the expression for  $u$  given in (15), we have

$$\left(\frac{d}{dx} + a\right)\left(\frac{d}{dx} + a\right)^{-1} v = v.$$

The inverse procedure is thus presented as one, *the effect of which the direct operation simply annuls*. This is its *definition*.

Thus in Arithmetic, division is inverse to multiplication. What is meant by dividing  $a$  by  $b$  is the seeking of a third number  $c$ , which when multiplied by  $b$  will produce  $a$ . And the very procedure by which this is effected consists not in any new and distinct operation for determining the subject  $c$ , but in a series of guesses, suggested by our prior *general* knowledge of the results of multiplication, and tested by multiplication.

And generally, if  $\pi$  represent any operation or series of operations possible when their subject is given, and then termed *direct*, and if, in the equation  $\pi u = v$ , the subject  $u$  be not given but only the result  $v$ , then we may write

$$u = \pi^{-1}v.$$

And the problem or inquiry contained in the inverse notation of the second member will be answered, when we have, by whatsoever process, so determined the function  $u$  as to satisfy the equation  $\pi u = v$  or  $\pi\pi^{-1}v = v$ . By the latter equation the inverse symbol  $\pi^{-1}$  is defined. Thus it is the office of the inverse symbol to propose a question, not to describe an operation. It is, in its primary meaning, interrogative, not directive.

Suppose the given equation to be

$$\left(\frac{d^n}{dx^n} + A_1 \frac{d^{n-1}}{dx^{n-1}} \dots + A_n\right) u = v \dots\dots\dots (16).$$

Then on the above principle of notation we should have

$$u = \left(\frac{d^n}{dx^n} + A_1 \frac{d^{n-1}}{dx^{n-1}} \dots + A_n\right)^{-1} v,$$

or, with not less propriety of expression,

$$u = \frac{1}{\frac{d^n}{dx^n} + A_1 \frac{d^{n-1}}{dx^{n-1}} \dots + A_n} v,$$

the last two equations differing in interpretation from (16), not at all as touching the *relation* between  $u$  and  $v$ , but only as more distinctly presenting  $u$  as the object of search.

Of what avail then, it may be asked, is that analogy upon which the expression of the last two equations is founded?

If a convention, it is at least a very natural one, that we should express an operation performed upon a subject, by attaching, in some way, the symbol denoting the operation to the symbol denoting the subject. The order of writing, in that family of languages to which our own belongs, has

doubtless determined the mode of connexion actually adopted, and which is the same as if the symbol of operation were a symbol of quantity employed as a coefficient or multiplier. It comes to pass, moreover, that the formal laws of combination in the *direct* cases investigated in Art. 2 prove to be the same for the symbol  $\frac{d}{dx}$  as for a coefficient or multiplier. But inverse symbols derive their meaning from the direct operations to which they stand related: they are forms of interrogation, the answers to which are to be tested by the performance of the direct operations. Hence it may be inferred that the laws for the transformations of inverse expressions involving  $\frac{d}{dx}$  with constants will be the same as for the corresponding forms of ordinary algebra. The analogy consists, not in the mere adoption of a common notation, but, as all true analogy does, in the similitude of relations.

#### 4. *Solution of Linear Equations with constant Coefficients.*

If the equation  $\left(\frac{d}{dx} - a\right)u = X$  be given, we have

$$u = \left(\frac{d}{dx} - a\right)^{-1} X,$$

but, the known general solution of the given equation being

$$u = e^{ax} \int e^{-ax} X dx,$$

we see that

$$\left(\frac{d}{dx} - a\right)^{-1} X = e^{ax} \int e^{-ax} X dx \dots\dots\dots(17),$$

an arbitrary constant being introduced by the integration in the second member.

If  $X = 0$ , we have

$$\left(\frac{d}{dx} - a\right)^{-1} X = C e^{ax} \dots\dots\dots(18).$$

These results we shall have occasion to refer to.

Ex. Now suppose the given equation to be

$$\frac{d^2u}{dx^2} - (a + b) \frac{du}{dx} + abu = X,$$

we have, on separating the symbols,

$$\left\{ \frac{d^2}{dx^2} - (a + b) \frac{d}{dx} + ab \right\} u = X,$$

or, by Art. 2,

$$\left( \frac{d}{dx} - a \right) \left( \frac{d}{dx} - b \right) u = X \dots \dots \dots (19).$$

Hence 
$$\left( \frac{d}{dx} - b \right) u = \left( \frac{d}{dx} - a \right)^{-1} X,$$

$$u = \left( \frac{d}{dx} - b \right)^{-1} \left( \frac{d}{dx} - a \right)^{-1} X \dots \dots \dots (20).$$

On comparing this with (19) we see that, in inverting a system composed of two operations performed in succession, the order of the operations themselves is inverted. This is evidently true whatever may be the number of successive operations, the last to be performed being always the first to be inverted.

From (20) we might deduce the actual value of  $u$  by successive applications of (17). Such was the method once employed. But it is better to proceed as follows.

From (19) we have

$$u = \left\{ \left( \frac{d}{dx} - a \right) \left( \frac{d}{dx} - b \right) \right\}^{-1} X \dots \dots \dots (21).$$

Now by the known theory of the decomposition of rational fractions

$$\{(m - a)(m - b)\}^{-1} = N_1 (m - a)^{-1} + N_2 (m - b)^{-1} \dots \dots (22),$$

$N_1, N_2$  being functions of  $a$  and  $b$ , which may be determined in various ways, but most *directly* by multiplying both sides of the equation by  $(m - a)(m - b)$ , and equating coefficients.

Now the suggested transformation of the expression for  $u$  given in (21) is

$$\left\{ \left( \frac{d}{dx} - a \right) \left( \frac{d}{dx} - b \right) \right\}^{-1} X = N_1 \left( \frac{d}{dx} - a \right)^{-1} X + N_2 \left( \frac{d}{dx} - b \right)^{-1} X \dots (23).$$

And, from the very definition of inverse forms, the proper test of the validity of this transformation is, that the performance of the direct operation  $\left( \frac{d}{dx} - a \right) \left( \frac{d}{dx} - b \right)$  on the second member shall reduce it to  $X$ .

Effecting this operation, and remembering in so doing that  $\frac{d}{dx} - a$  and  $\frac{d}{dx} - b$  are commutative, and that by definition  $\left( \frac{d}{dx} - a \right) \left( \frac{d}{dx} - a \right)^{-1} X = X$ , the second member becomes

$$N_1 \left( \frac{d}{dx} - b \right) X + N_2 \left( \frac{d}{dx} - a \right) X,$$

$$\text{or} \quad (N_1 + N_2) \frac{dX}{dx} - (bN_1 + aN_2) X \dots \dots \dots (24),$$

and this reduces to  $X$  if

$$N_1 + N_2 = 0, \quad bN_1 + aN_2 = -1 \dots \dots \dots (25).$$

But these equations for the determination of  $N_1$  and  $N_2$  are the same, and necessarily the same, as we should have found by multiplying, as above indicated, (22), by  $(m - a)(m - b)$ , and equating coefficients. The two series of operations only differ in that  $\frac{d}{dx}$  occupies in the one the place which  $m$  occupies in the other. Determining  $N_1, N_2$ , we see that  $u$  may be expressed in the form

$$u = \frac{1}{a - b} \left\{ \left( \frac{d}{dx} - a \right)^{-1} X - \left( \frac{d}{dx} - b \right)^{-1} X \right\} \dots \dots \dots (26).$$

Hence, by (17),

$$u = \frac{1}{a-b} \left\{ \epsilon^{ax} \int \epsilon^{-ax} X dx - \epsilon^{bx} \int \epsilon^{-bx} X dx \right\} \dots\dots\dots (27),$$

and as, on effecting the integrations, two arbitrary constants will be introduced, this is the most general value of  $u$ .

5. In like manner if there be given the general linear differential equation with constant coefficients

$$\left( \frac{d^n}{dx^n} + A_1 \frac{d^{n-1}}{dx^{n-1}} + A_2 \frac{d^{n-2}}{dx^{n-2}} \dots + A_n \right) u = X \dots\dots\dots (28),$$

and if we represent by  $a_1, a_2, \dots a_n$  the roots, supposed all different, of the algebraic equation

$$m^n + A_1 m^{n-1} + A_2 m^{n-2} \dots + A_n = 0 \dots\dots\dots (29),$$

then the given equation may be expressed in the form

$$\left( \frac{d}{dx} - a_1 \right) \left( \frac{d}{dx} - a_2 \right) \dots \left( \frac{d}{dx} - a_n \right) u = X,$$

whence

$$\begin{aligned} u &= \left\{ \left( \frac{d}{dx} - a_1 \right) \left( \frac{d}{dx} - a_2 \right) \dots \left( \frac{d}{dx} - a_n \right) \right\}^{-1} X \\ &= \left\{ N_1 \left( \frac{d}{dx} - a_1 \right)^{-1} + N_2 \left( \frac{d}{dx} - a_2 \right)^{-1} \dots + N_n \left( \frac{d}{dx} - a_n \right)^{-1} \right\} X^* \dots (30), \end{aligned}$$

the decomposition in the second member formally resembling that of the rational fraction.

If the equation (29) have  $r$  roots equal to  $a$ , there will exist in the resolved expression for  $u$  a series of terms of the form

$$\left\{ N_1 \left( \frac{d}{dx} - a \right)^{-r} + N_2 \left( \frac{d}{dx} - a \right)^{-r+1} \dots + N_r \left( \frac{d}{dx} - a \right)^{-1} \right\} X \dots\dots\dots (31),$$

\* This theorem was first published in the *Cambridge Mathematical Journal* (1st series, Vol. II. p. 114), in a memoir written by the late D. F. Gregory, then Editor of the Journal, from notes furnished by the author of this work, whose name the memoir bears. The illustrations were supplied by Mr Gregory. In mentioning these circumstances the author recalls to memory a brief but valued friendship. [See a note on page 108 of Boole's *Finite Differences*, 1860.]

or, which is preferable, a single term of the form

$$\left(A + B \frac{d}{dx} + C \frac{d^2}{dx^2} \dots + R \frac{d^{r-1}}{dx^{r-1}}\right) \left(\frac{d}{dx} - a\right)^{-r} X \dots \dots (32),$$

$A, B, \dots R$  being determinate constants.

$$\text{Now since, by (17), } \left(\frac{d}{dx} - a\right)^{-1} X = \epsilon^{ax} \int \epsilon^{-ax} X dx;$$

$$\begin{aligned} \text{therefore } \left(\frac{d}{dx} - a\right)^{-2} X &= \left(\frac{d}{dx} - a\right)^{-1} \epsilon^{ax} \int \epsilon^{-ax} X dx \\ &= \epsilon^{ax} \int \epsilon^{-ax} (\epsilon^{ax} \int \epsilon^{-ax} X dx) dx \\ &= \epsilon^{ax} \iint \epsilon^{-ax} X dx^2. \end{aligned}$$

Proceeding thus, we have

$$\left(\frac{d}{dx} - a\right)^{-r} X = \epsilon^{ax} \int \dots \epsilon^{-ax} X dx^r \dots \dots \dots (33).$$

$$\text{Ex. 1. Given } \frac{d^4 y}{dx^4} + 4 \frac{d^3 y}{dx^3} + 3 \frac{d^2 y}{dx^2} - 4 \frac{dy}{dx} - 4y = X.$$

This equation gives, on decomposing the complex operation performed on  $y$ ,

$$\left(\frac{d}{dx} + 2\right)^2 \left(\frac{d}{dx} + 1\right) \left(\frac{d}{dx} - 1\right) y = X;$$

$$\text{therefore } y = \left\{ \left(\frac{d}{dx} + 2\right)^2 \left(\frac{d}{dx} + 1\right) \left(\frac{d}{dx} - 1\right) \right\}^{-1} X.$$

$$\text{Now } \frac{1}{(m+2)^2(m+1)(m-1)} = \frac{4m+11}{9(m+2)^2} - \frac{1}{2(m+1)} + \frac{1}{18(m-1)}.$$

Therefore

$$\begin{aligned} y &= \frac{1}{9} \left(4 \frac{d}{dx} + 11\right) \left(\frac{d}{dx} + 2\right)^{-2} X - \frac{1}{2} \left(\frac{d}{dx} + 1\right)^{-1} X + \frac{1}{18} \left(\frac{d}{dx} - 1\right)^{-1} X \\ &= \frac{1}{9} \left(4 \frac{d}{dx} + 11\right) \epsilon^{-2x} \iint \epsilon^{2x} X dx^2 - \frac{1}{2} \epsilon^{-x} \int \epsilon^x X dx + \frac{1}{18} \epsilon^x \int \epsilon^{-x} X dx. \end{aligned}$$

Ex. 2. Given  $\frac{d^2u}{dx^2} + n^2u = X$ .

Here  $u = \left(\frac{d^2}{dx^2} + n^2\right)^{-1} X$ .

Now  $(m^2 + n^2)^{-1} = \frac{1}{2n\sqrt{-1}} [\{m - n\sqrt{-1}\}^{-1} - \{m + n\sqrt{-1}\}^{-1}]$ .

Hence  $u = \frac{1}{2n\sqrt{-1}} \left[ \left\{ \frac{d}{dx} - n\sqrt{-1} \right\}^{-1} X - \left\{ \frac{d}{dx} + n\sqrt{-1} \right\}^{-1} X \right]$   
 $= \frac{1}{2n\sqrt{-1}} \left\{ \epsilon^{nx\sqrt{-1}} \int \epsilon^{-nx\sqrt{-1}} X dx - \epsilon^{-nx\sqrt{-1}} \int \epsilon^{nx\sqrt{-1}} X dx \right\}.$

But  $\epsilon^{nx\sqrt{-1}} \int \epsilon^{-nx\sqrt{-1}} X dx$

$= \{\cos nx + \sqrt{-1} \sin nx\} \left\{ \int \cos nx X dx - \sqrt{-1} \int \sin nx X dx \right\}$

$\epsilon^{-nx\sqrt{-1}} \int \epsilon^{nx\sqrt{-1}} X dx$

$= \{\cos nx - \sqrt{-1} \sin nx\} \left\{ \int \cos nx X dx + \sqrt{-1} \int \sin nx X dx \right\},$

whence, on substitution and reduction,

$$u = \frac{1}{n} \left\{ \sin nx \int \cos nx X dx - \cos nx \int \sin nx X dx \right\}.$$

6. When the second member  $X$  is a rational and integral function of  $x$ , the final integration may be avoided. For, representing the given equation in the form  $f\left(\frac{d}{dx}\right)u = X + 0$ , we have

$$u = \left\{ f\left(\frac{d}{dx}\right) \right\}^{-1} X + \left\{ f\left(\frac{d}{dx}\right) \right\}^{-1} 0 \dots \dots \dots (34).$$

A particular value of the first term will be obtained by developing  $\left\{ f\left(\frac{d}{dx}\right) \right\}^{-1}$  in ascending powers (so to speak) of  $\frac{d}{dx}$ , and then performing the differentiations on  $X$ , while the general value of the second term will introduce the requisite number of arbitrary constants.

Ex. Given  $\frac{d^2 u}{dx^2} + n^2 u = 1 + x + x^2$ .

$$\begin{aligned} \text{Here } u &= \left( \frac{d^2}{dx^2} + n^2 \right)^{-1} (1 + x + x^2) + \left( \frac{d^2}{dx^2} + n^2 \right)^{-1} 0 \\ &= (n^{-2} - n^{-4} \frac{d^2}{dx^2} + n^{-6} \frac{d^4}{dx^4} - \&c.) (1 + x + x^2) \\ &\quad + C_1 \cos nx + C_2 \sin nx \\ &= n^{-2} (1 + x + x^2) - 2n^{-4} + C_1 \cos nx + C_2 \sin nx. \end{aligned}$$

The validity of the transformation of the inverse form  $\left( \frac{d^2}{dx^2} + n^2 \right)^{-1}$  by development, as of its other transformation by decomposition, is tested by performing on the result the direct operation  $\frac{d^2}{dx^2} + n^2$ . We take occasion to notice that different transformations, while equally valid, do not of necessity conduct us to solutions equally general, nor have we any right to expect that they should. Each solution is an answer to the question contained in the given inverse form, but that question may admit of different answers, and no solution is *general* which does not include them all.

The final integrations may also be avoided when  $X$  consists of a series of exponentials of the form  $\epsilon^{mx}$  with coefficients which are either constants, or rational and integral functions of  $x$ .

Since  $\left( \frac{d}{dx} \right)^n \epsilon^{mx} = m^n \epsilon^{mx}$ , we have, for all interpretable forms of  $f\left( \frac{d}{dx} \right)$ , the relation

$$f\left( \frac{d}{dx} \right) \epsilon^{mx} = f(m) \epsilon^{mx} \dots\dots\dots (35),$$

the second member expressing the complete, because the only, value of the first member when  $f\left( \frac{d}{dx} \right)$  is rational and integral,

but a particular value of the first member when  $f\left(\frac{d}{dx}\right)$  is inverse, the test being as before.

Hence, if the given equation be  $f\left(\frac{d}{dx}\right)u = \Sigma A_m \epsilon^{mx}$ , we have

$$\begin{aligned} u &= \left\{f\left(\frac{d}{dx}\right)\right\}^{-1} \Sigma A_m \epsilon^{mx} + \left\{f\left(\frac{d}{dx}\right)\right\}^{-1} 0 \\ &= \Sigma A_m \{f(m)\}^{-1} \epsilon^{mx} + \left\{f\left(\frac{d}{dx}\right)\right\}^{-1} 0 \dots\dots\dots (36), \end{aligned}$$

the second term introducing the requisite number of arbitrary constants.

Again, if, in any expression of the form  $f\left(\frac{d}{dx}\right)\epsilon^{mx}X$ , we convert  $\frac{d}{dx}$  into  $\frac{d_1}{dx} + \frac{d_2}{dx}$ , where  $\frac{d_1}{dx}$  operates on  $x$  only as contained in  $\epsilon^{mx}$ , and  $\frac{d_2}{dx}$  operates on  $x$  only as contained in  $X$ , we have

$$\begin{aligned} f\left(\frac{d}{dx}\right)\epsilon^{mx}X &= f\left(\frac{d_1}{dx} + \frac{d_2}{dx}\right)\epsilon^{mx}X \\ &= f\left(m + \frac{d_2}{dx}\right)\epsilon^{mx}X, \text{ by (35)} \\ &= \epsilon^{mx}f\left(m + \frac{d_2}{dx}\right)X. \end{aligned}$$

Hence, dropping the suffix which is no longer necessary, since  $X$  alone follows the operative symbol, we have

$$f\left(\frac{d}{dx}\right)\epsilon^{mx}X = \epsilon^{mx}f\left(\frac{d}{dx} + m\right)X \dots\dots\dots (37).$$

When therefore  $X$  is a rational and integral function of  $x$ , a particular value of the first member may be found from the

second, by developing the functional symbol and effecting the differentiations. And that particular value may be made general, as in the following example.

Ex. Given  $\frac{d^2u}{dx^2} - 3\frac{du}{dx} + 2u = x\epsilon^{mx}$ .

$$\begin{aligned}\text{Here } u &= \left\{ \left( \frac{d}{dx} - 1 \right) \left( \frac{d}{dx} - 2 \right) \right\}^{-1} x\epsilon^{mx} + \left\{ \left( \frac{d}{dx} - 1 \right) \left( \frac{d}{dx} - 2 \right) \right\}^{-1} 0 \\ &= \epsilon^{mx} \left\{ \left( \frac{d}{dx} + m - 1 \right) \left( \frac{d}{dx} + m - 2 \right) \right\}^{-1} x + C_1\epsilon^x + C_2\epsilon^{2x} \\ &= \epsilon^{mx} \left\{ \frac{1}{(m-1)(m-2)} - \frac{2m-3}{\{(m-1)(m-2)\}^2} \frac{d}{dx} + \&c. \right\} x \\ &\quad + C_1\epsilon^x + C_2\epsilon^{2x} \\ &= \frac{x\epsilon^{mx}}{(m-1)(m-2)} - \frac{(2m-3)\epsilon^{mx}}{\{(m-1)(m-2)\}^2} + C_1\epsilon^x + C_2\epsilon^{2x}.\end{aligned}$$

Again, the theorem (37) relieves us from any difficulty arising from cases of failure referred to in Chap. IX. Art. 9.

Ex. Given  $\left( \frac{d}{dx} - a \right)^n u = \epsilon^{ax}$ .

$$\begin{aligned}\text{Here } u &= \left( \frac{d}{dx} - a \right)^{-n} \epsilon^{ax} = \epsilon^{ax} \left( \frac{d}{dx} \right)^{-n} 1 \text{ by (37)} \\ &= \epsilon^{ax} \left( c_1 + c_2x \dots + c_{n-1}x^{n-1} + \frac{x^n}{1 \cdot 2 \dots n} \right).\end{aligned}$$

When the second member  $X$  involves terms of the form  $A \cos mx$ ,  $B \sin mx$ , &c., we may either substitute for them their exponential values, or we may employ directly the easily demonstrated theorem

$$f\left(\frac{d^2}{dx^2}\right) \frac{\sin}{\cos} mx = f(-m^2) \frac{\sin}{\cos} mx.$$

Ex. Given  $\frac{d^2 u}{dx^2} + n^2 u = \Sigma a_m \cos (mx + b)$ .

$$\begin{aligned} \text{Here } u &= \left( \frac{d^2}{dx^2} + n^2 \right)^{-1} \Sigma a_m \cos (mx + b) + \left( \frac{d^2}{dx^2} + n^2 \right)^{-1} 0 \\ &= \Sigma \frac{a_m \cos (mx + b)}{n^2 - m^2} + C_1 \cos nx + C_2 \sin nx. \end{aligned}$$

In this example, however, the failing case which represents itself when  $m = n$ , is most simply, though not most satisfactorily, treated by the methods of Chap. IX. Art. 11.

The reduction of an integral of the  $n^{\text{th}}$  order by the foregoing theory is not devoid of elegance.

We have

$$\iint \dots X dx^n = \left( \frac{d}{dx} \right)^{-n} X.$$

Now let  $x = e^\theta$ , then

$$\frac{dX}{dx} = e^{-\theta} \frac{dX}{d\theta},$$

$$\frac{d^2 X}{dx^2} = e^{-\theta} \frac{d}{d\theta} e^{-\theta} \frac{dX}{d\theta} = e^{-2\theta} \left( \frac{d}{d\theta} - 1 \right) \frac{d}{d\theta} X, \text{ by (37).}$$

Proceeding thus, we have

$$\frac{d^n}{dx^n} X = e^{-n\theta} \left( \frac{d}{d\theta} - n + 1 \right) \left( \frac{d}{d\theta} - n + 2 \right) \dots \frac{d}{d\theta} X \dots (38),$$

and therefore the operation denoted by  $\left( \frac{d}{dx} \right)^n$ , and the compound operation denoted by

$$e^{-n\theta} \left( \frac{d}{d\theta} - n + 1 \right) \left( \frac{d}{d\theta} - n + 2 \right) \dots \frac{d}{d\theta},$$

are absolutely equivalent. Hence inverting both, and observing that the inversion of the latter involves the inversion of the order of its component symbols, we have

$$\begin{aligned}
\left(\frac{d}{dx}\right)^{-n} X &= \left\{ \left(\frac{d}{d\theta} - n + 1\right) \left(\frac{d}{d\theta} - n + 2\right) \dots \frac{d}{d\theta} \right\}^{-1} \epsilon^{n\theta} X \\
&= \frac{1}{1 \cdot 2 \dots (n-1)} \left\{ \left(\frac{d}{d\theta} - n + 1\right)^{-1} - (n-1) \left(\frac{d}{d\theta} - n + 2\right)^{-1} \right. \\
&\quad \left. + \frac{(n-1)(n-2)}{1 \cdot 2} \left(\frac{d}{d\theta} - n + 3\right)^{-1} - \&c. \right\} \epsilon^{n\theta} X \\
&= \frac{1}{1 \cdot 2 \dots (n-1)} \left\{ \epsilon^{(n-1)\theta} \left(\frac{d}{d\theta}\right)^{-1} \epsilon^\theta - (n-1) \epsilon^{(n-2)\theta} \left(\frac{d}{d\theta}\right)^{-1} \epsilon^{2\theta} + \&c. \right\} X \\
&= \frac{1}{1 \cdot 2 \dots (n-1)} \left\{ x^{n-1} \int X dx - (n-1) x^{n-2} \int X x dx \right. \\
&\quad \left. + \frac{(n-1)(n-2)}{1 \cdot 2} x^{n-3} \int X x^2 dx \dots \pm \int X x^{n-1} dx \right\},
\end{aligned}$$

the result in question.

From (38) we have the theorem

$$x^n \frac{d^n}{dx^n} = \frac{d}{d\theta} \left( \frac{d}{d\theta} - 1 \right) \dots \left( \frac{d}{d\theta} - n + 1 \right) \dots \dots \dots (39),$$

which is important in the transformation of differential equations.

### *Forms purely symbolical.*

7. In any system in which thought is expressed by symbols, the laws of combination of the symbols are determined from the study of the corresponding operations in thought. But it may be that the latter are subject to *conditions of possibility* as well as to laws *when possible*. And thus it may be that two systems of symbols, differing in interpretation, may agree as to their formal laws whenever they both express operations possible in thought, while at the same time there may exist combinations which really represent thought in the one but do not in the other. For instance, there exist forms of the functional symbol  $f$ , for which we can attach a meaning to the expression  $f(m)$ , but cannot directly attach a meaning

to the symbol  $f\left(\frac{d}{dx}\right)$ . And the question arises: Does this difference restrict our freedom in the use of that principle which permits us to treat expressions of the form  $f\left(\frac{d}{dx}\right)$  as if  $\frac{d}{dx}$  were a symbol of quantity? For instance, we can attach no *direct* meaning to the expression  $\epsilon^{h\frac{d}{dx}}f(x)$ , but if we develop the exponential as if  $\frac{d}{dx}$  were quantitative, we have

$$\begin{aligned}\epsilon^{h\frac{d}{dx}}f(x) &= \left(1 + h\frac{d}{dx} + \frac{1}{1.2}h^2\frac{d^2}{dx^2} + \&c.\right)f(x) \\ &= f(x+h) \text{ by Taylor's theorem.}\end{aligned}$$

Are we then permitted, on the above principle, to make use of symbolic language; always supposing that we can, by the continued application of the same principle, obtain a *final* result of interpretable form?

Now all special instances point to the conclusion that this is permissible, and seem to indicate, as a general principle, that the mere processes of symbolical reasoning are independent of the conditions of their interpretation. In the few instances we may have occasion to employ, verification will be easy. We take occasion to notice that, whatever view may be taken of this principle, whether it be contemplated as belonging to the realm of *a priori* truth, or whether it be regarded as a generalization from experience, it would be an error to regard it as in any peculiar sense a mathematical principle. It claims a place among the *general* relations of Thought and Language.

On the principle above stated we should have

$$\begin{aligned}\epsilon^{h\frac{d}{dx}+k\frac{d}{dy}}f(x,y) &= \epsilon^{h\frac{d}{dx}}\epsilon^{k\frac{d}{dy}}f(x,y) \\ &= f(x+h, y+k).\end{aligned}$$

And here, the expression  $\epsilon^{h\frac{d}{dx}+k\frac{d}{dy}}$ , which is without meaning in itself, is to be regarded simply as the representative of the expression

$$1 + h\frac{d}{dx} + k\frac{d}{dy} + \frac{1}{1.2}\left(h\frac{d}{dx} + k\frac{d}{dy}\right)^2 + \frac{1}{1.2.3}\left(h\frac{d}{dx} + k\frac{d}{dy}\right)^3 + \&c.,$$

which has meaning. And the proper test of the validity of the symbolic equation

$$\epsilon^{h\frac{d}{dx}+k\frac{d}{dy}} = \epsilon^{h\frac{d}{dx}} \epsilon^{k\frac{d}{dy}}$$

consists in substituting for each exponential form the series it represents, and comparing the finally developed results, just as we should, by developing the exponentials, verify the algebraic equation,

$$\epsilon^{hm+kn} = \epsilon^{hm} \epsilon^{kn}.$$

It must be noted that  $\frac{d}{dx}$  and  $\frac{d}{dy}$  are commutative, and combine, in all respects, like symbols of quantity. We are not permitted to write  $\epsilon^{x+\frac{d}{dx}} = \epsilon^x \epsilon^{\frac{d}{dx}}$ , because  $x$  and  $\frac{d}{dx}$  are not commutative.

8. The above principle is illustrated in the solution of the following partial differential equations.

Ex. Given  $\frac{d^2 u}{dx^2} - a^2 \frac{d^2 u}{dy^2} = \phi(x, y).$

$$\begin{aligned} \text{Here } u &= \left(\frac{d^2}{dx^2} - a^2 \frac{d^2}{dy^2}\right)^{-1} \phi(x, y) \\ &= \left(2a \frac{d}{dy}\right)^{-1} \left\{ \left(\frac{d}{dx} - a \frac{d}{dy}\right)^{-1} - \left(\frac{d}{dx} + a \frac{d}{dy}\right)^{-1} \right\} \phi(x, y) \\ &= \left(2a \frac{d}{dy}\right)^{-1} \left\{ \epsilon^{ax\frac{d}{dy}} \int \epsilon^{-ax\frac{d}{dy}} \phi(x, y) dx - \epsilon^{-ax\frac{d}{dy}} \int \epsilon^{ax\frac{d}{dy}} \phi(x, y) dx \right\} \\ &= \frac{1}{2a} \int \left\{ \Phi_1(x, y + ax) - \Phi_2(x, y - ax) \right\} dy, \end{aligned}$$

the forms of  $\Phi_1$  and  $\Phi_2$  being given by the equations

$$\Phi_1(x, y) = \int \phi(x, y - ax) dx + \psi(y),$$

$$\Phi_2(x, y) = \int \phi(x, y + ax) dx + \chi(y),$$

$\psi(y)$  and  $\chi(y)$  being arbitrary functions of  $y$ .

If  $\phi(x, y) = 0$ , we hence find

$$u = \frac{1}{2a} \int \left\{ \psi(y + ax) - \chi(y - ax) \right\} dy,$$

or, if we represent  $\frac{1}{2a} \int \psi(y) dy$  by  $\psi_1(y)$ , and  $\frac{1}{2a} \int \chi(y) dy$  by  $\chi_1(y)$ ,

$$u = \psi_1(y + ax) + \chi_1(y - ax).$$

As  $\psi$  and  $\chi$  are arbitrary,  $\psi_1$  and  $\chi_1$  are so too. This agrees with the result on p. 370.

Ex. Given  $\frac{d^2 u}{dx^2} + \frac{d^2 u}{dy^2} + \frac{d^2 u}{dz^2} = 0$ .

We may put this in the form  $\frac{d^2 u}{dx^2} + au = 0$ , where  $a$  stands for  $\frac{d^2}{dy^2} + \frac{d^2}{dz^2}$ , and integrate with respect to  $x$ , as if  $a$  were a constant quantity. Remembering that the two arbitrary constants of the complete integral must then be replaced by two arbitrary functions of  $y, z$ , we get the symbolical solution

$$u = \cos \left\{ x \left( \frac{d^2}{dy^2} + \frac{d^2}{dz^2} \right)^{\frac{1}{2}} \right\} \phi(y, z) + \sin \left\{ x \left( \frac{d^2}{dy^2} + \frac{d^2}{dz^2} \right)^{\frac{1}{2}} \right\} \psi(y, z).$$

Developing the cosine and the sine, and replacing

$$\left( \frac{d^2}{dy^2} + \frac{d^2}{dz^2} \right)^{\frac{1}{2}} \psi(y, z)$$

by a new arbitrary function  $\chi(y, z)$ , we have

$$\begin{aligned}
u = & \phi(y, z) - \frac{x^2}{1.2} \left( \frac{d^2}{dy^2} + \frac{d^2}{dz^2} \right) \phi(y, z) \\
& + \frac{x^4}{1.2.3.4} \left( \frac{d^2}{dy^2} + \frac{d^2}{dz^2} \right)^2 \phi(y, z) - \&c. \\
+ & x\chi(y, z) - \frac{x^3}{1.2.3} \left( \frac{d^2}{dy^2} + \frac{d^2}{dz^2} \right) \chi(y, z) \\
& + \frac{x^5}{1.2.3.4.5} \left( \frac{d^2}{dy^2} + \frac{d^2}{dz^2} \right)^2 \chi(y, z) - \&c.
\end{aligned}$$

Under this form, the solution is presented by Lagrange in the *Mécanique Analytique*, Tom. II. p. 320.

*Generalization of the foregoing theory.*

9. All equations, whatsoever their nature or subject, which are expressible in the form

$$(\pi^n + A_1\pi^{n-1} + A_2\pi^{n-2} \dots + A_n) u = X \dots (1),$$

where  $\pi$  is an operative symbol subject to the laws

$$\pi a u = a \pi u, \quad \pi(u + v) = \pi u + \pi v, \quad \pi^m \pi^n u = \pi^{m+n} u,$$

$a$  being a constant and  $u$  and  $v$  functions of  $x$ , admit of transformations analogous to those of Art. 5.

Thus, since  $u = (\pi^n + A_1\pi^{n-1} + A_2\pi^{n-2} \dots + A_n)^{-1} X$ ,

we shall have, when the roots  $a_1, a_2, \dots, a_n$  of the auxiliary equation

$$m^n + A_1 m^{n-1} + A_2 m^{n-2} \dots + A_n = 0$$

are real and unequal, the transformation

$$u = N_1 (\pi - a_1)^{-1} X + N_2 (\pi - a_2)^{-1} X \dots + N_n (\pi - a_n)^{-1} X \dots (2),$$

the coefficients  $N_1, N_2, \dots, N_n$  being determined as in Art. 5.

The *legitimacy* of this transformation is proved by operating on both sides of (2) with  $\pi^n + A_1\pi^{n-1} \dots + A_n$ , and shewing

that (1) is reproduced with the same conditions for determining  $N_1, N_2, \dots, N_n$  as if  $\pi$  were a symbol of quantity. But the question of its *completeness*, of its conducting, through the performance of the inverse operations  $(\pi - a_1)^{-1}$ , &c., to the most *general* solution of (1), is one that we are not called upon to determine *a priori*. In all the cases we shall have to consider, its completeness will be obvious.

Ex. The equation  $\frac{d^2u}{dx^2} - (2x+1)\frac{du}{dx} + (x^2+x-1)u = 0$  is reducible to the form  $\pi(\pi-1)u = 0$  where  $\pi = \frac{d}{dx} - x$ . Hence

$$u = (\pi - 1)^{-1} 0 - \pi^{-1} 0.$$

Let  $(\pi - 1)^{-1} 0 = y$ , then, since  $(\pi - 1)y = 0$ , we have

$$\frac{dy}{dx} - (x+1)y = 0, \quad y = c_1 \epsilon^{\frac{(x+1)^2}{2}}.$$

In like manner, if  $\pi^{-1} 0 = z$ , we find

$$\frac{dz}{dx} - xz = 0, \quad z = c_2 \epsilon^{\frac{x^2}{2}}.$$

Therefore  $u = c_1 \epsilon^{\frac{(x+1)^2}{2}} - c_2 \epsilon^{\frac{x^2}{2}}.$

A very interesting application of the same theory to the solution of partial differential equations is afforded by what Mr Carmichael has termed the index symbol of homogeneous functions. *Cambridge and Dublin Math. Journal*, Vol. VI. p. 277.

Since, if  $u_a$  represent a homogeneous function of the  $a^{\text{th}}$  degree of the variables  $x_1, x_2, \dots, x_n$ , we have

$$x_1 \frac{du_a}{dx_1} + x_2 \frac{du_a}{dx_2} \dots + x_n \frac{du_a}{dx_n} = au_a \dots \dots \dots (3),$$

it follows that, if we represent the symbol  $x_1 \frac{d}{dx_1} \dots + x_n \frac{d}{dx_n}$  by  $\pi$ , we shall have

$$\pi u_a = au_a, \quad \pi^2 u_a = a^2 u_a, \quad \&c.$$

and therefore, in accordance with the reasoning of Arts. 3 and 4,

$$f(\pi) u_a = f(a) u_a \dots\dots\dots (A),$$

an equation of which the second member expresses the complete, because the only, value of the first member when  $f(\pi)$  is rational and integral, but a particular value when the first member contains inverse factors.

Hence, if we have any equation  $f(\pi) u = X$ , where  $f(\pi)$  is of the form  $\pi^n + A_1 \pi^{n-1} + A_2 \pi^{n-2} \dots + A_n$ , and  $X$  is a series of homogeneous functions of the variables, suppose

$$X = X_a + X_b + \dots \&c.,$$

we get

$$\begin{aligned} u &= \{f(\pi)\}^{-1} X + \{f(\pi)\}^{-1} 0 \\ &= \{f(\pi)\}^{-1} X_a + \{f(\pi)\}^{-1} X_b \dots + \{f(\pi)\}^{-1} 0 \\ &= \{f(a)\}^{-1} X_a + \{f(b)\}^{-1} X_b \dots + \{f(\pi)\}^{-1} 0, \text{ by } (A). \end{aligned}$$

To find the value of the last term, we proceed, as in Art. 5, to reduce it to a series of terms of the form  $A_i (\pi - a)^{-i} 0$ ,  $i$  being the number of roots equal to  $a$  of the equation  $f(m) = 0$ . Now it may, by an induction founded on successive applications of Lagrange's method for the solution of linear partial differential equations of the first order, be shewn that

$$(\pi - a)^{-i} 0 = u_a (\log x_1)^{i-1} + v_a (\log x_1)^{i-2} \dots + w_a \dots (B),$$

$u_a, v_a, \dots, w_a$  being arbitrary homogeneous functions of  $x_1, x_2, \dots, x_n$  of the  $a^{\text{th}}$  degree.

To this result we may give the symmetrical form

$$(\pi - a)^{-i} 0 = u_a L^{i-1} + v_a M^{i-2} \dots + w_a,$$

$L, M, \&c.$  being logarithms of any homogeneous functions which are not of the degree 0.

It remains to shew how it may be ascertained whether a proposed partial differential equation can be reduced to the form  $f(\pi) u = X$ .

Let us resolve each symbol  $\frac{d}{dx_i}$ , entering into  $\pi$ , into two, and let  $\frac{d'}{dx_i}$  represent  $\frac{d}{dx_i}$  as operating on  $x_i$  only as entering into  $u$ , and  $\frac{d''}{dx_i}$  only as entering into  $\pi$ . Also let

$$x_1 \frac{d'}{dx_1} + x_2 \frac{d'}{dx_2} \dots + \&c. = \pi', \text{ and } x_1 \frac{d''}{dx_1} + x_2 \frac{d''}{dx_2} + \&c. = \pi''.$$

It is easily seen then that  $\pi = \pi' + \pi''$ . We have therefore  $\pi' u = (\pi - \pi'') u = \pi u$ ;

therefore  $\pi'^2 u = (\pi - \pi'') \pi u \dots\dots\dots (C).$

But as  $\pi''$ , in  $(C)$ , operates on the variables only as entering into  $\pi$ , which is a homogeneous function of those variables of the first degree, we may replace it by unity. We have therefore  $\pi'^2 u = (\pi - 1) \pi u$ . In the same way it may be shewn that  $\pi'^r u = (\pi - r + 1) (\pi - r + 2) \dots \pi u$ . And thus it is seen that any partial differential equation which is expressible in the form  $f(\pi) u = X$ , on the hypothesis that  $\frac{d}{dx_1}, \frac{d}{dx_2}, \&c.$  operate on the variables only as entering into  $u$ , is reducible to the form  $\phi(\pi) u = X$ , independently of such restriction. This reduction having been effected, the solution can be found by means of  $(A)$  and  $(B)$ , whenever the second member consists of one or more homogeneous functions of  $x_1, x_2, \dots x_n$ .

$$\begin{aligned} \text{Ex. } x^2 \frac{d^2 u}{dx^2} + 2xy \frac{d^2 u}{dxdy} + y^2 \frac{d^2 u}{dy^2} - n \left( x \frac{du}{dx} + y \frac{du}{dy} \right) + nu \\ = x^2 + y^2 + x^3. \end{aligned}$$

Here we have  $(\pi'^2 - n\pi' + n) u = x^2 + y^2 + x^3$ .

Therefore  $\{\pi(\pi - 1) - n\pi + n\} u = x^2 + y^2 + x^3$ ,

or  $(\pi - n)(\pi - 1) u = x^2 + y^2 + x^3$ ,

whence

$$\begin{aligned} u &= \{(\pi - n)(\pi - 1)\}^{-1} \{x^2 + y^2 + x^3\} + \{(\pi - n)(\pi - 1)\}^{-1} 0 \\ &= \frac{x^2 + y^2}{(2 - n)(2 - 1)} + \frac{x^3}{(3 - n)(3 - 1)} + u_n + v_1, \end{aligned}$$

$u_n, v_1$  denoting arbitrary homogeneous functions of the degree  $n$  and 1 respectively.

10. We may, by simple transformations, reduce to the above case various other classes of equations differing from the above only as to the form of  $\pi$ ; e.g. the class in which  $\pi = a_1 x_1 \frac{d}{dx_1} + a_2 x_2 \frac{d}{dx_2} \dots + a_n x_n \frac{d}{dx_n}$ ; but, passing over such special forms, we shall consider the general equation  $f(\pi)u = X$ , where

$$\pi = X_1 \frac{d}{dx_1} + X_2 \frac{d}{dx_2} \dots + X_n \frac{d}{dx_n},$$

and each of the coefficients  $X_1, X_2, \dots, X_n$ , as well as  $X$ , may be any function whatever of the independent variables. And we design to shew, first, how it may be determined whether a given equation admits of reduction to the more general form above proposed; secondly, how, then, to integrate it.

Suppose the given equation of the  $n^{\text{th}}$  order; then the symbolical form in question, should the proposed reduction be possible, will be

$$(\pi^n + A_1 \pi^{n-1} + A_2 \pi^{n-2} \dots + A_n) u = X \dots \dots \dots (4).$$

Now the highest differential coefficients in the given equation will arise solely from the symbol  $\pi^n$ , and the terms in which they occur will enable us to determine the form of  $\pi$ . Thus, for two variables, we have

$$\begin{aligned} \left(M \frac{d}{dx} + N \frac{d}{dy}\right)^2 u &= M^2 \frac{d^2 u}{dx^2} + 2MN \frac{d^2 u}{dxdy} + N^2 \frac{d^2 u}{dy^2} \\ &+ \left(M \frac{dM}{dx} + N \frac{dM}{dy}\right) \frac{du}{dx} + \left(M \frac{dN}{dx} + N \frac{dN}{dy}\right) \frac{du}{dy}, \end{aligned}$$

in which the terms containing  $\frac{d^3u}{dx^2}$ ,  $\frac{d^2u}{dxdy}$ ,  $\frac{d^2u}{dy^2}$  are the same as they would be, if, in the first member,  $\frac{d}{dx}$ ,  $\frac{d}{dy}$  were symbols of quantity. And this law is general for the *highest* differential coefficients.

Again, the form of  $\pi$  being determined, the values of  $A_1, A_2, \dots$  will, whenever the proposed reduction is possible, be found by effecting the operations implied in the first member of (4), and comparing with the first member of the equation given.

Suppose the equation reduced to the form (4). Then, if the auxiliary equation

$$m^n + A_1 m^{n-1} + A_2 m^{n-2} \dots + A_n = 0 \dots \dots \dots (5)$$

have its roots all unequal, we have a series of terms of the form  $(\pi - \alpha)^{-1}X$ ; and each such term involves the solution of a partial differential equation of the first order of the form

$$X_1 \frac{du}{dx_1} + X_2 \frac{du}{dx_2} \dots + X_n \frac{du}{dx_n} - au = X.$$

But, if the auxiliary equation (5) have equal roots, partial differential equations of higher orders will present themselves. We deem it therefore important to shew how this difficulty may be avoided, or, to speak more precisely, how its solution may be made to flow from that of the corresponding case of linear differential equations with constant coefficients.

Introduce a new system of independent variables  $y_1, y_2, \dots y_n$ , so conditioned as to give  $\pi = \frac{d}{dy_1}$ . To prove that such a system exists, and to discover it, let us assume  $y_1, y_2, \dots y_n$ , in succession, as subjects of the above symbolical equation, and examine whether the results are consistent. And first, assuming  $y_1$  as subject, we have

$$X_1 \frac{dy_1}{dx_1} + X_2 \frac{dy_1}{dx_2} \dots \dots + X_n \frac{dy_1}{dx_n} = 1 \dots \dots \dots (6).$$

Secondly, assuming  $y_i$ , representative of any of the remaining variables  $y_2, y_3, \dots y_n$ , as subject, we have the equation

$$X_1 \frac{dy_i}{dx_1} + X_2 \frac{dy_i}{dx_2} \dots + X_n \frac{dy_i}{dx_n} = 0 \dots \dots \dots (7).$$

It follows from the above that, if we integrate the auxiliary system

$$\frac{dx_1}{X_1} = \frac{dx_2}{X_2} \dots = \frac{dx_n}{X_n} \dots \dots \dots (8),$$

the values of  $y_2, y_3, \dots y_n$  will be the first members of the integrals of that system expressed in the form

$$y_2 = a_2, y_3 = a_3 \dots y_n = a_n \dots \dots \dots (9).$$

And it follows from (6) that if, from the system

$$\frac{dx_1}{X_1} = \frac{dx_2}{X_2} \dots = \frac{dx_n}{X_n} = dy_1 \dots \dots \dots (10),$$

differing from (8) only in that it contains one additional member  $dy_1$ , we deduce an additional integral equation connecting  $y_1$  with the original variables  $x_1, x_2, \dots x_n$ , that equation will give the value of  $y_1$ . We see that the number of distinct auxiliary equations is precisely equal to the number of quantities to be determined, so that the scheme is a consistent one.

The solution of the problem is therefore virtually dependent on the partial differential equation (6), from the auxiliary system of which, (10), it suffices to deduce  $n$  integrals, one expressing  $y_1$  in terms of  $x_1, x_2, \dots x_n$ , the others determining  $y_2, y_3, \dots y_n$ , as functions of  $x_1, x_2, \dots x_n$ , in the forms (9). To the arbitrary constant in the value of  $y_1$  we may give any value we please.

Introducing the new variables, the equation given now assumes the form

$$f\left(\frac{d}{dy_1}\right) u = \phi(y_1, y_2, \dots y_n),$$

which must be integrated as if  $u$  and  $y_1$  were the only variables, an arbitrary function of  $y_2, y_3, \dots y_n$  being introduced in the place of an arbitrary constant. Finally, we must restore to  $y_1, y_2, \dots y_n$  their values in terms of  $x_1, x_2, \dots x_n$ .

Ex. Given  $(1-x^2)^2 \frac{d^2 u}{dx^2} + 2(1-x^2)(1-xy) \frac{d^2 u}{dx dy} + (1-xy)^2 \frac{d^2 u}{dy^2} - 2x(1-x^2) \frac{du}{dx} - (x+y-2x^2y) \frac{du}{dy} + n^2 u = 0.$

Here, the form of the first three terms shews that we must have  $\pi = (1-x^2) \frac{d}{dx} + (1-xy) \frac{d}{dy}$ , and the equation assumes the form

$$(\pi^2 + n^2) u = 0.$$

To avoid the difficulty arising from the imaginary factors of  $\pi^2 + n^2$ , let us assume two new variables,  $x'$  and  $y'$ , such that we may have  $\pi = \frac{d}{dx'}$ . Then by (10)

$$\frac{dx}{1-x^2} = \frac{dy}{1-xy} = dx',$$

corresponding to which we have the integral systems

$$\frac{y-x}{\sqrt{(1-x^2)}} = c, \quad x' = \log \sqrt{\left(\frac{1+x}{1-x}\right)} + c'.$$

Hence, if we assume

$$x' = \log \sqrt{\left(\frac{1+x}{1-x}\right)}, \quad y' = \frac{y-x}{\sqrt{(1-x^2)}},$$

we get the transformed equation

$$\left(\frac{d^2}{dx'^2} + n^2\right) u = 0;$$

therefore  $u = \cos nx' \phi(y') + \sin nx' \psi(y')$ ,

or, restoring to  $x'$  and  $y'$  their values,

$$u = \cos \left\{ n \log \sqrt{\left(\frac{1+x}{1-x}\right)} \right\} \phi \frac{y-x}{\sqrt{(1-x^2)}} + \sin \left\{ n \log \sqrt{\left(\frac{1+x}{1-x}\right)} \right\} \psi \frac{y-x}{\sqrt{(1-x^2)}}.$$

## EXERCISES.

$$1. \quad \frac{d^3 y}{dx^3} - 2 \frac{d^2 y}{dx^2} + \frac{dy}{dx} = e^x.$$

$$2. \quad \frac{d^2 u}{dx^2} - 5 \frac{du}{dx} + 6u = e^{mx}.$$

3. Determine the solution of the above equation when  $m = 2$ .

$$4. \quad \frac{d^2 u}{dx^2} - 9 \frac{du}{dx} + 20u = x^2 e^{3x}.$$

$$5. \quad \frac{d^2 u}{dx^2} + 3 \frac{du}{dx} + 2u = \cos mx.$$

$$6. \quad \text{Solve the equation } \left( \frac{d}{dx} - a \right)^n u = \cos mx.$$

In the above example it will be most convenient to proceed thus :

$$\begin{aligned} u &= \left( \frac{d}{dx} - a \right)^{-n} \cos mx + \left( \frac{d}{dx} - a \right)^{-n} 0 \\ &= \frac{\left( \frac{d}{dx} + a \right)^n}{\left( \frac{d^2}{dx^2} - a^2 \right)^n} \cos mx + e^{ax} \left( \frac{d}{dx} \right)^{-n} 0 \\ &= \frac{1}{(-m^2 - a^2)^n} \left( \frac{d}{dx} + a \right)^n \cos mx + e^{ax} (c_1 + c_2 x \dots + c_n x^{n-1}). \end{aligned}$$

$$7. \quad \text{Solve the equation } \left( \frac{d}{dx} - a \right)^n u = e^x \cos mx.$$

$$8. \quad x^2 \frac{d^2 u}{dx^2} + 2xy \frac{d^2 u}{dx dy} + y^2 \frac{d^2 u}{dy^2} - n \left( x \frac{du}{dx} + y \frac{du}{dy} - u \right) = 0.$$

$$9. \quad x^2 \frac{d^2 u}{dx^2} + 2xy \frac{d^2 u}{dx dy} + y^2 \frac{d^2 u}{dy^2} = (x^2 + y^2)^{\frac{n}{2}}.$$

10. Solve, by the method of Art. 10, the equation

$$\left(x \frac{d}{dx} + y \frac{d}{dy} + z \frac{d}{dz}\right)^2 u + n^2 u = 0.$$

11. The solution of any equation of the form

$$\frac{d^2 u}{dx^2} + (2X + a) \frac{du}{dx} + \left(\frac{dX}{dx} + X^2 + aX + b\right) u = 0$$

may be reduced to that of two linear equations of the first order.

## CHAPTER XVII.

## SYMBOLICAL METHODS, CONTINUED.

1. THE classes of equations considered in the last chapter might all be gathered up into the one larger class represented by

$$f(\pi) u = X,$$

$\pi$  being a symbol combining with constant quantities as if it were itself a symbol of quantity. But linear differential equations do not, except under particular conditions, admit of expression in this form. Those which are of the ordinary species involve in their general expression two symbols,  $x$  and  $\frac{d}{dx}$ , operating in combination on the sought and dependent variable  $y$ ; and no substituted form of such equations is *general* which introduces fewer than two symbols in the place of  $x$  and  $\frac{d}{dx}$ . We propose in this chapter to employ a transformation which is general, and which is adapted in a very remarkable degree to the development of general methods of solution. A somewhat fuller account of it will be found in a memoir on a General Method in Analysis (*Philosophical Transactions* for 1844, Part II.). Other principles and other methods will also be noticed.

The following theorems, demonstrated in Chap. XVI., will frequently recur.

If  $x = \epsilon^\theta$ , and if  $\frac{d}{d\theta}$  be represented by  $D$ , then

$$x^n \frac{d^n u}{dx^n} = D(D-1) \dots (D-n+1) u \dots \dots \dots (1),$$

while the relations connecting  $\frac{d}{d\theta}$  and  $\epsilon^\theta$  become

$$f(D) \epsilon^{m\theta} = f(m) \epsilon^{m\theta} \dots\dots\dots (2),$$

$$f(D) \epsilon^{m\theta} u = \epsilon^{m\theta} f(D + m) u \dots\dots\dots (3).$$

The latter of these relations enables us to transfer the exponential  $\epsilon^{m\theta}$  from one side of the expression  $f(D)$  to the other, by changing  $D$  into  $D \pm m$ , according as the transference is from right to left or from left to right. Thus, as another form of (3), we should have

$$\epsilon^{m\theta} f(D) u = f(D - m) \epsilon^{m\theta} u \dots\dots\dots (4).$$

It is an immediate consequence of the above theorem that *every linear differential equation which can be expressed in the form,*

$$(a + bx + cx^2 \dots) \frac{d^n u}{dx^n} + (a' + b'x + c'x^2 \dots) \frac{d^{n-1} u}{dx^{n-1}} + \&c. = X \dots (5),$$

*can be reduced to the symbolical form,*

$$f_0(D) u + f_1(D) \epsilon^\theta u + f_2(D) \epsilon^{2\theta} u + \&c. = T \dots\dots\dots (6),$$

*where  $T$  is a function of  $\theta$ .*

For multiplying the given equation by  $x^n$ , and assuming  $x = \epsilon^\theta$ , the first term of the left-hand member becomes, by (1),

$$(a + b\epsilon^\theta + c\epsilon^{2\theta} + \&c.) D(D - 1) \dots (D - n + 1) u,$$

and this is reducible, by (4), to the form

$$aD(D - 1) \dots (D - n + 1) u + b(D - 1)(D - 2) \dots (D - n) \epsilon^\theta u \\ + c(D - 2)(D - 3) \dots (D - n - 1) \epsilon^{2\theta} u + \&c.,$$

each term of which is of the general form  $\phi(D) \epsilon^{i\theta} u$ . The other terms of the first member of (5) admitting of a similar reduction, while the second member becomes a function of  $\theta$ , the equation itself assumes the symbolical form (6).

Ex. 1. Given  $\frac{d^2 u}{dx^2} - n^2 u = 0$ .

Multiplying by  $x^2$ , and transforming as above, we get

$$D(D - 1) u - n^2 \epsilon^{2\theta} u = 0.$$

Ex. 2. Given  $(1 + ax^2) \frac{d^2u}{dx^2} + ax \frac{du}{dx} \pm n^2u = \phi(x)$ .

Multiplying by  $x^2$ , we have, by (1),

$$(1 + a\epsilon^{2\theta}) D(D-1)u + a\epsilon^{2\theta} Du \pm n^2\epsilon^{2\theta}u = \epsilon^{2\theta}\phi(\epsilon^\theta).$$

But

$$\epsilon^{2\theta}D(D-1)u = (D-2)(D-3)\epsilon^{2\theta}u; \text{ and } \epsilon^{2\theta}Du = (D-2)\epsilon^{2\theta}u,$$

whence, substituting, and collecting together terms like with respect to the exponentials, we have

$$D(D-1)u + \{a(D-2)^2 \pm n^2\}\epsilon^{2\theta}u = \epsilon^{2\theta}\phi(\epsilon^\theta)$$

as the symbolical form.

To return from the symbolical to the ordinary form of a differential equation, we must, by (3), transfer the exponentials to the *left* of each symbolic function  $f(D)$ , convert the latter into a series of factorials of the form  $D(D-1)\dots(D-n+1)$ , and then apply the transformation (1).

Ex. 3. Given  $D(D-1)u + D(D+1)\epsilon^\theta u = 0$ .

We have in succession,

$$D(D-1)u + \epsilon^\theta(D+1)(D+2)u = 0,$$

$$D(D-1)u + \epsilon^\theta\{D(D-1) + 4D + 2\}u = 0,$$

$$x^2 \frac{d^2u}{dx^2} + x(x^2 \frac{d^2u}{dx^2} + 4x \frac{du}{dx} + 2u) = 0.$$

Therefore, dividing by  $x$ ,

$$(x + x^2) \frac{d^2u}{dx^2} + 4x \frac{du}{dx} + 2u = 0.$$

A symbolical equation which has only two terms in its first member may be termed a binomial equation; one which has three terms a trinomial equation, and so on. We may determine by inspection to which of these classes an ordinary differential equation is reducible. For multiplying it by such a power of  $x$  as to permit its expression in the form

$$Ax^n \frac{d^n y}{dx^n} + Bx^{n-1} \frac{d^{n-1} y}{dx^{n-1}} + \&c. = X,$$

where  $A$ ,  $B$ , &c. are algebraic polynomials with respect to  $x$ , the number of *distinct* powers of  $x$  involved in those polynomials will determine the number of terms in the reduced symbolical equation.

Ex. 4. Thus the equation

$$(a + bx) \frac{d^2 u}{dx^2} + (c + ex) \frac{du}{dx} + qu = 0,$$

being expressed in the form

$$(a + bx) x^2 \frac{d^2 u}{dx^2} + (cx + ex^2) x \frac{du}{dx} + (qx^2) u,$$

it is seen that its symbolical form will be trinomial, since the terms within the brackets involve  $x$  in the degrees 0, 1, and 2.

[See the *Supplementary Volume*, Chapter xxx. Art. 1.]

*Finite solution of differential equations expressed in the symbolical form.*

2. If we affect both sides of the symbolical equation (6) with  $\{f_0(D)\}^{-1}$ , then for  $f_0(D)^{-1}f_1(D)$  write  $\phi_1(D)$  &c. and for  $\{f_0(D)\}^{-1}T$  write  $U$ , we shall have

$$u + \phi_1(D) \epsilon^\theta u + \phi_2(D) \epsilon^{2\theta} u \dots + \phi_n(D) \epsilon^{n\theta} u = U \dots \dots \dots (7);$$

and under this form the equation will be discussed in the following section.

PROP. I. *The equation*

$$u + \alpha_1 \phi(D) \epsilon^\theta u + \alpha_2 \phi(D) \phi(D-1) \epsilon^{2\theta} u \dots \\ + \alpha_n \phi(D) \phi(D-1) \dots \phi(D-n+1) \epsilon^{n\theta} u = U \dots (8)$$

may be resolved into a system of equations of the form

$$u - q\phi(D) \epsilon^\theta u = U,$$

the values of  $q$  being determined by the equation

$$q^n + a_1 q^{n-1} + a_2 q^{n-2} \dots + a_n = 0.$$

For

$$\phi(D) \phi(D-1) \epsilon^{2\theta} u = \phi(D) \epsilon^\theta \phi(D) \epsilon^\theta u = \{\phi(D) \epsilon^\theta\}^2 u,$$

and in general

$$\phi(D) \phi(D-1) \dots \phi(D-n+1) \epsilon^{n\theta} u = \{\phi(D) \epsilon^\theta\}^n u.$$

So that, if we represent the symbol  $\phi(D) \epsilon^\theta$  by  $\rho$ , the equation in question becomes

$$(1 + a_1 \rho + a_2 \rho^2 \dots + a_n \rho^n) u = U;$$

therefore

$$u = (1 + a_1 \rho + a_2 \rho^2 \dots + a_n \rho^n)^{-1} U$$

$$= \{N_1 (1 - q_1 \rho)^{-1} + N_2 (1 - q_2 \rho)^{-1} \dots + N_n (1 - q_n \rho)^{-1}\} U,$$

provided that  $q_1, q_2 \dots q_n$  are roots of the equation

$$q^n + a_1 q^{n-1} + a_2 q^{n-2} \dots + a_n = 0,$$

and that  $N_1, N_2 \dots N_n$  are of the forms

$$N_1 = \frac{q_1^{n-1}}{(q_1 - q_2)(q_1 - q_3) \dots (q_1 - q_n)} \\ \dots \dots \dots N_n = \frac{q_n^{n-1}}{(q_n - q_1)(q_n - q_2) \dots (q_n - q_{n-1})}.$$

Let  $(1 - q_1 \rho)^{-1} U = u_1$ ,  $(1 - q_2 \rho)^{-1} U = u_2$ , and so on, then

$$u = N_1 u_1 + N_2 u_2 \dots + N_n u_n,$$

where, in general,  $u_i$  is given by the solution of the equation

$$u_i - q_i \phi(D) \epsilon^\theta u_i = U \dots \dots \dots (9).$$

The solution of the general equation (8) is therefore dependent on that of the binomial equation (9).

When  $\phi(D)$  is of the form  $D^{-1}$  the equation (8) corresponds to the ordinary linear differential equation with constant coefficients.

Thus the equation  $u - \frac{q^2}{D(D-1)} \epsilon^{2\theta} u = 0$ , which may be integrated by the above process, is only the symbolical form of the equation  $\frac{d^2 u}{dx^2} - q^2 u = 0$  (see Ex. 1); and its solution, expressed in terms of  $x$ , is

$$u = C\epsilon^{qx} + C'\epsilon^{-qx}.$$

In like manner the equation  $u + \frac{q^2}{D(D-1)} \epsilon^{2\theta} u = 0$  has for its solution, expressed in terms of  $x$ ,

$$u = C \cos qx + C' \sin qx.$$

But, when  $\phi(D)$  is not of the form  $D^{-1}$ , the equation (8) will represent an ordinary equation with variable coefficients.

Ex. 5. Given

$$(x^2 - 3x^3 + 2x^4) \frac{d^2 u}{dx^2} + (4x - 6x^2) \frac{du}{dx} + (2 + 6x) u = ax^n.$$

The symbolical form of this equation is

$$(D+1)(D+2)u - 3(D+1)(D-2)\epsilon^\theta u + 2(D-2)(D-3)\epsilon^{2\theta} u = a\epsilon^{n\theta},$$

whence

$$u - 3 \frac{D-2}{D+2} \epsilon^\theta u + 2 \frac{(D-2)(D-3)}{(D+2)(D+1)} \epsilon^{2\theta} u = \frac{a\epsilon^{n\theta}}{(n+2)(n+1)},$$

or, putting  $\frac{D-2}{D+2} \epsilon^\theta = \rho, \quad \frac{a\epsilon^{n\theta}}{(n+2)(n+1)} = T,$

$$(1 - 3\rho + 2\rho^2) u = T.$$

Hence  $u = \frac{1}{1 - 3\rho + 2\rho^2} T = \left( \frac{2}{1 - 2\rho} - \frac{1}{1 - \rho} \right) T$   
 $= 2u_1 - u_2 \dots\dots\dots (a),$

where  $u_1 = (1 - 2\rho)^{-1} T, \quad u_2 = (1 - \rho)^{-1} T.$

From the former we have

$$(1 - 2\rho) u_1 = T, \text{ or } u_1 - 2 \frac{D-2}{D+2} \epsilon^\theta u_1 = \frac{\alpha \epsilon^{n\theta}}{(n+2)(n+1)},$$

whence  $(D+2) u_1 - 2(D-2) \epsilon^\theta u_1 = \frac{\alpha \epsilon^{n\theta}}{n+1};$

and this gives  $(x - 2x^2) \frac{du_1}{dx} + (2 + 2x) u_1 = \frac{\alpha x^n}{n+1} \dots\dots\dots (b).$

In like manner we find, for  $u_2$ ,

$$(x - x^2) \frac{du_2}{dx} + (2 + x) u_2 = \frac{\alpha x^n}{n+1} \dots\dots\dots (c).$$

The values of  $u_1$  and  $u_2$ , determined from (b) and (c), and substituted in (a), will give the complete solution.

If  $\alpha = 0$ , we find  $u = \frac{C_1(1-2x)^3 + C_2(1-x)^3}{x^3}.$

3. We proceed to consider more fully the theory of the binomial equation

$$u + \phi(D) \epsilon^{r\theta} u = U \dots\dots\dots (10).$$

PROP. II. *The equation  $u + \phi(D) \epsilon^{r\theta} u = U$  will be converted into  $v + \phi(D+n) \epsilon^{r\theta} v = V$ , by the relations*

$$u = \epsilon^{n\theta} v, \quad U = \epsilon^{n\theta} V.$$

For assume  $u = \epsilon^{n\theta} v$ , and, substituting in the original equation, we have

$$\epsilon^{n\theta} v + \phi(D) \epsilon^{(n+r)\theta} v = U;$$

therefore  $\epsilon^{n\theta} v + \epsilon^{n\theta} \phi(D+n) \epsilon^{r\theta} v = U$ , by (3),

$$v + \phi(D+n) \epsilon^{r\theta} v = \epsilon^{-n\theta} U.$$

Let  $U = \epsilon^{n\theta} V$ ; then the above becomes

$$v + \phi(D+n) \epsilon^{r\theta} v = V,$$

as was to be shewn.

*Thus in any binomial equation we can convert  $\phi(D)$  into  $\phi(D+n)$ ,  $n$  being any constant.*

PROP. III. *The equation  $u + \phi(D) \epsilon^{r\theta} u = U$  will be converted into  $v + \psi(D) \epsilon^{r\theta} v = V$ , by the relations,*

$$u = P_r \frac{\phi(D)}{\psi(D)} v, \quad U = P_r \frac{\phi(D)}{\psi(D)} V,$$

where  $P_r \frac{\phi(D)}{\psi(D)}$  denotes the symbolical product

$$\frac{\phi(D) \phi(D-r) \phi(D-2r) \dots}{\psi(D) \psi(D-r) \psi(D-2r) \dots}.$$

For, assume  $u = f(D) v$ , and, substituting in the original equation, we have

$$f(D) v + \phi(D) \epsilon^{r\theta} f(D) v = U;$$

therefore  $f(D) v + \phi(D) f(D-r) \epsilon^{r\theta} v = U$ , by (4),

$$v + \frac{\phi(D) f(D-r)}{f(D)} \epsilon^{r\theta} v = \{f(D)\}^{-1} U \dots \dots \dots (11).$$

Comparing this with the equation  $v + \psi(D) \epsilon^{r\theta} v = V$ , we have

$$\frac{\phi(D) f(D-r)}{f(D)} = \psi(D);$$

therefore  $f(D) = \frac{\phi(D)}{\psi(D)} f(D-r).$

Hence  $f(D-r) = \frac{\phi(D-r)}{\psi(D-r)} f(D-2r),$

and so on; wherefore the value of  $f(D)$  will be represented by the infinite product  $\frac{\phi(D) \phi(D-r) \phi(D-2r) \dots}{\psi(D) \psi(D-r) \psi(D-2r) \dots}$ . Hence (11) becomes

$$v + \psi(D) \epsilon^{r\theta} v = V$$

with the relations

$$u = P_r \frac{\phi(D)}{\psi(D)} v, \quad U = P_r \frac{\phi(D)}{\psi(D)} V \dots \dots \dots (12).$$

As this proposition is of great importance in the solution of differential equations, it will be proper to examine the conditions which its application involves. Evidently they consist in such a choice of the form of  $\psi(D)$  as will render the symbolical product  $P_r \frac{\phi(D)}{\psi(D)}$  finite, and the transformed equation (11) integrable.

That the expression of  $P_r \frac{\phi(D)}{\psi(D)}$  may be finite, it is sufficient that for every elementary factor  $\chi(D)$  occurring in the numerator there should correspond a similar factor  $\chi(D \pm ir)$  in the denominator,  $i$  being any integer or 0; and *vice versa*; for

$$\begin{aligned} P_r \frac{\chi(D)}{\chi(D+ir)} &= \frac{\chi(D) \chi(D-r) \chi(D-2r) \dots}{\chi(D+ir) \chi\{D+(i-1)r\} \dots} \\ &= \frac{1}{\chi(D+ir) \chi\{D+(i-1)r\} \dots \chi(D+r)}, \end{aligned}$$

which is a finite expression. Again

$$\begin{aligned} P_r \frac{\chi(D)}{\chi(D-ir)} &= \frac{\chi(D) \chi(D-r) \dots}{\chi(D-ir) \chi\{D-(i+1)r\} \dots} \\ &= \chi(D) \chi(D-r) \dots \chi\{D-(i-1)r\}, \end{aligned}$$

which is also finite; the product of any number of such expressions is finite also.

Hence, if  $\chi(D)$  be any elementary factor of  $\phi(D)$ , it may be converted into  $\chi(D \pm ir)$ ; for let  $\phi(D) = \chi(D) \chi_1(D)$ , and let  $\psi(D) = \chi(D \pm ir) \chi_1(D)$ , wherein  $\chi_1(D)$  denotes the product of the remaining factors, then

$$P_r \frac{\phi(D)}{\psi(D)} = P_r \frac{\chi(D)}{\chi(D \pm ir)},$$

which is finite.

Hence also, if  $\phi(D)$  involve any factor of the form  $\frac{\chi(D)}{\chi(D \pm ir)}$ , it may be made to disappear; for let  $\phi(D) = \frac{\chi(D)}{\chi(D \pm ir)} \chi_1(D)$ ,

and let  $\psi(D) = \chi_1(D)$ , then

$$P_r \frac{\phi(D)}{\psi(D)} = P_r \frac{\chi(D)}{\chi(D \pm ir)},$$

which is finite.

[See the *Supplementary Volume*, Chapter xxx. Art. 3.]

4. We see, then, that there are two distinct kinds of transformation to which the Proposition may be applied. In the first kind  $\phi(D)$  is converted into another symbolic function  $\psi(D)$  without any loss of component factors, whether of numerator or of denominator, but only with such change as consists in the conversion of  $D$  into  $D \pm ir$ . And here the order of the transformed equation is the same as that of the equation given, and, its solution introducing a sufficient number of arbitrary constants, no others need to be introduced, either in the prior determination of  $V$  or in the subsequent derivation of  $u$ . But in the second species of transformation some component factor of  $\phi(D)$  (usually of the form  $\frac{D+a}{D+b}$  where  $a-b$  is a multiple of  $r$ ) is lost, and the transformed equation being of an order lower than that of the equation given, the deficient constants of its solution must be supplied, either beforehand in the determination of  $V$ , or subsequently in the derivation of  $u$ . If in the former, any constants, sufficient in number, introduced by the performance of  $\left\{ P_r \frac{\phi(D)}{\psi(D)} \right\}^{-1} U$  will serve the purpose. If in the latter, all the constants introduced by the performance of  $P_r \frac{\phi(D)}{\psi(D)} v$  must be retained, but their subsequent relation must be determined by means of the differential equation.

[See the *Supplementary Volume*, Chapter xxx. Art. 4.]

The reason why the constants connected with the disappearing factors are arbitrary in  $V$  alone, is, that  $V$  enters into no other equation than the one in whose solution those constants are found. If, however, the entire series of constants in  $V$  be retained, they will be reduced by the subsequent differentiations in passing to the value of  $u$ .

All that may seem obscure in the above statement will be made clear by the following examples.

Ex. 6. Given  $\frac{d^2u}{dx^2} + q^2u - \frac{6u}{x^2} = 0$ , an equation occurring in the theory of the earth's figure.

The symbolical form is

$$u + \frac{q^2}{(D+2)(D-3)} \epsilon^{2\theta} u = 0 \dots\dots\dots(a).$$

Now we may, by Prop. III, directly reduce this equation to the form

$$v + \frac{q^2}{(D+2)(D+1)} \epsilon^{2\theta} v = 0,$$

which, by Prop. I, is resolvable into two equations of the first order. But it is better to assume as the transformed equation

$$v + \frac{q^2}{D(D-1)} \epsilon^{2\theta} v = 0 \dots\dots\dots(b),$$

the solution of which is known already. Art. 2.

By Prop. II, assuming  $u = \epsilon^{-2\theta} w$ , we have

$$w + \frac{q^2}{D(D-5)} \epsilon^{2\theta} w = 0 \dots\dots\dots(c).$$

Again, by Prop. III, we can pass from (c) to (b) by assuming

$$w = P_2 \frac{D-1}{D-5} v = (D-1)(D-3) v.$$

Hence  $u = \epsilon^{-2\theta} (D-1)(D-3) v$

$$= \epsilon^{-2\theta} \{D(D-1) - 3D + 3\} v$$

$$= \frac{1}{x^2} \left( x^2 \frac{d^2}{dx^2} - 3x \frac{d}{dx} + 3 \right) c \sin(qx + c')$$

on restoring  $x$  and putting for  $v$  its value in terms of  $x$ .

Effecting the differentiations, we find

$$u = c \left\{ \left( \frac{3}{x^2} - q^2 \right) \sin (qx + c') - \frac{3q}{x} \cos (qx + c') \right\} \dots\dots (d).$$

We might have proceeded directly from (a) to (b) by Prop. III; but, had we done so, the final reductions would not have depended on differentiations alone. Thus we should have had

$$\begin{aligned} u &= P_2 \frac{D(D-1)}{(D+2)(D-3)} v = \frac{D-1}{D+2} v \\ &= \{1 - 3(D+2)^{-1}\} v = (1 - 3\epsilon^{-2\theta} D^{-1} \epsilon^{2\theta}) v \\ &= v - 3\epsilon^{-2\theta} \int \epsilon^{2\theta} v d\theta, \end{aligned}$$

whence, restoring  $x$  and giving to  $v$  its previous value, we should be led to the same solution as before.

5. The two forms of solution above presented illustrate an important observation, viz. that when in the transition from  $\phi(D)$  to  $\psi(D)$ , by Prop. III, the reductions consist in augmenting, if we may be allowed the expression,  $D$  in factors of the denominator of  $\phi(D)$ , or in diminishing  $D$  in factors of the numerator, they will be effected by differentiations; while those reductions which consist in augmenting  $D$  in factors of the numerator of  $\phi(D)$ , or diminishing it in factors of the denominator, involve integrations. And it is one use of Prop. II, that it enables us, in many cases, so to prepare the given symbolical equation that the final reductions shall depend on differentiations.

Ex. 7. It is required to determine the symbolical form and character of those differential equations of the  $n^{\text{th}}$  order, the solution of which depends on that of the equation

$$\frac{d^n v}{dx^n} \pm q^n v = X.$$

The symbolical form of this equation is

$$v \pm \frac{q^n}{D(D-1)\dots(D-n+1)} \epsilon^{n\theta} v = V \dots\dots (a),$$

where  $V$  is the symbolical form of  $\left(\frac{d}{dx}\right)^{-n} X$ , i.e. the result

obtained by writing  $\epsilon^\theta$  for  $x$  in the  $n^{\text{th}}$  integral of  $Xdx^n$ , no constants being added in the integration. From inspection of (a), it is evident that the class of equations sought must, on assuming  $x = \epsilon^\theta$ , be expressible in the form

$$u \pm \frac{q^n}{(D + a_1)(D + a_2) \dots (D + a_n)} \epsilon^{n\theta} u = U \dots (b),$$

in which we shall suppose the quantities  $a_1, a_2 \dots a_n$  to be ranged in the order of decreasing magnitude. Put  $u = \epsilon^{-a_1\theta} u_1$ , then by Prop. II,

$$u_1 \pm \frac{q^n}{D(D + a_2 - a_1) \dots (D + a_n - a_1)} \epsilon^{n\theta} u_1 = \epsilon^{a_1\theta} U \dots (c).$$

The first factor of the denominator of  $\phi(D)$  in (c) now agrees with the first factor in that of  $\psi(D)$  in (a). In any of the remaining factors we may, by Prop. III, convert  $D$  into  $D \pm in$ ,  $i$  being any integer,—hence, that they may all correspond with the factors of  $\psi(D)$ , it is necessary that each of the quantities

$$\frac{a_2 - a_1 + 1}{n}, \frac{a_3 - a_1 + 2}{n}, \frac{a_4 - a_1 + 3}{n}, \dots, \frac{a_n - a_1 + n - 1}{n} \dots (d),$$

should be equal to a negative integer or to 0. And in this statement the conditions of finite solution are involved.

The value of  $u$  will be deduced from that of  $v$  by *differentiation*, for since  $a_2 - a_1 < -1$ ,

$$P_n \frac{D-1}{(D + a_2 - a_1)} = (D-1)(D-n+1) \dots (D + a_2 - a_1 + n),$$

and so on for the remaining factors to which  $P_n$  is to be applied.

Ex. 8. Given  $\frac{d^2 u}{dx^2} - \frac{i(i+1)}{x^2} u \pm q^2 u = 0$ , where  $i$  is an integer.

This equation, which includes that of Ex. 6, presents itself in various physical problems (Poisson, *Théorie Mathématique de la Chaleur*, p. 158. Mossotti, on *Molecular Action*, &c.).

Its symbolical form is

$$u \pm \frac{q^2}{(D+i)(D-i-1)} \epsilon^{2\theta} u = 0 \dots \dots \dots (a).$$

Hence, by the last example,

$$\begin{aligned} u &= \epsilon^{-i\theta} P_2 \frac{D-1}{D-2i-1} v \\ &= \epsilon^{-i\theta} (D-1)(D-3) \dots (D-2i+1) v \dots \dots \dots (b), \end{aligned}$$

where  $v$  is given by  $\frac{d^2 v}{dx^2} \pm q^2 v = 0$ .

The expression  $(b)$  may be reduced to a more convenient form, as follows.

Since  $f(D-\alpha) = \epsilon^{\alpha\theta} f(D) \epsilon^{-\alpha\theta}$ , we have

$$\begin{aligned} u &= \epsilon^{-i\theta} \cdot \epsilon^\theta D \epsilon^{-\theta} \cdot \epsilon^{3\theta} D \epsilon^{-3\theta} \dots \epsilon^{(2i-1)\theta} D \epsilon^{-(2i-1)\theta} v \\ &= \epsilon^{-(i+1)\theta} \left( \epsilon^{2\theta} \frac{d}{d\theta} \right)^i \epsilon^{-(2i-1)\theta} v \\ &= x^{-(i+1)} \left( x^3 \frac{d}{dx} \right)^i x^{-(2i-1)} v. \end{aligned}$$

Hence, according as the upper or lower sign is taken in the original equation, we have

$$u = \frac{1}{x^{i+1}} \left( x^3 \frac{d}{dx} \right)^i \frac{c_1 \cos qx + c_2 \sin qx}{x^{2i-1}} \dots \dots \dots (c),$$

or

$$u = \frac{1}{x^{i+1}} \left( x^3 \frac{d}{dx} \right)^i \frac{c_1 \epsilon^{qx} + c_2 \epsilon^{-qx}}{x^{2i-1}} \dots \dots \dots (d).$$

Ex. 9. Given  $\frac{d^2 u}{dx^2} - a^2 \frac{d^2 u}{dy^2} - \frac{i(i+1)u}{x^2} = 0$ .

Comparing this equation with the last, we see that its solution may be derived from  $(d)$  by changing therein  $q$  into  $a \frac{d}{dy}$ , and  $c_1, c_2$  into arbitrary functions of  $y$  following the exponentials. Hence we shall have

$$\begin{aligned}
 u &= \frac{1}{x^{i+1}} \left( x^3 \frac{d}{dx} \right)^i \frac{\epsilon^{ax \frac{d}{dy}} \phi(y) + \epsilon^{-ax \frac{d}{dy}} \psi(y)}{x^{2i-1}} \\
 &= \frac{1}{x^{i+1}} \left( x^3 \frac{d}{dx} \right)^i \frac{\phi(y + ax) + \psi(y - ax)}{x^{2i-1}}.
 \end{aligned}$$

The reason why the arbitrary function  $\phi(y)$  must be placed after  $\epsilon^{ax \frac{d}{dy}}$  and not before it, is that, in the derivation of the exemplar form, the arbitrary constant takes its place after, and not before  $\epsilon^{qx}$ .

For 
$$\left( \frac{d}{dx} - q \right)^{-1} 0 = \epsilon^{qx} \left( \frac{d}{dx} \right)^{-1} 0 = \epsilon^{qx} c.$$

Here indeed we may transpose the constant, but when  $q$  is converted into  $a \frac{d}{dy}$  we have

$$\left( \frac{d}{dx} - a \frac{d}{dy} \right)^{-1} 0 = \epsilon^{ax \frac{d}{dy}} \left( \frac{d}{dx} \right)^{-1} 0 = \epsilon^{ax \frac{d}{dy}} \phi(y),$$

and here the arbitrary function cannot be transposed, since  $y$  and  $\frac{d}{dy}$  are not commutative.

The principle here illustrated, and which is a very important one, is that all conclusions founded on community of formal laws should stop short of interpretation. The *form* should be kept distinct from the *matter*. There is perfect analogy between the theorems

$$\left( \frac{d}{dx} - q \right)^{-1} 0 = \epsilon^{qx} \left( \frac{d}{dx} \right)^{-1} \epsilon^{-qx} 0,$$

and 
$$\left( \frac{d}{dx} - a \frac{d}{dy} \right)^{-1} 0 = \epsilon^{ax \frac{d}{dy}} \left( \frac{d}{dx} \right)^{-1} \epsilon^{-ax \frac{d}{dy}} 0,$$

but not between the theorems

$$\left( \frac{d}{dx} - q \right)^{-1} 0 = c \epsilon^{qx}, \text{ and } \left( \frac{d}{dx} - a \frac{d}{dy} \right)^{-1} 0 = \epsilon^{ax \frac{d}{dy}} \phi(y),$$

because in the formation of the latter interpretation has been employed.

The above example is one in which Monge's method of solution would fail, except for the particular case of  $i = 0$ . And this gives occasion to the remark that symbolical methods are not, as they have sometimes been supposed to be, valuable only as abbreviating the processes of analysis. There are innumerable cases in which they afford the only proper mode of procedure.

Ex. 10. Given

$$(1 - x^2) \frac{d^2 u}{dx^2} + \left\{ \frac{p+1}{x} - (4n-p+1)x \right\} \frac{du}{dx} - 2n(2n-p)u = 0.$$

This equation occurs in some researches of Poisson on definite integrals. The symbolical form is

$$u - \frac{(D+2n-2)(D+2n-2-p)}{D(D+p)} \epsilon^{2\theta} u = 0 \dots\dots(a).$$

This equation is integrable in several distinct cases, but we shall examine here the particular case in which  $n$  is an integer.

Assuming as the transformed equation,

$$v - \frac{D+2n-2-p}{D+p} \epsilon^{2\theta} v = V \dots\dots(b),$$

it being necessary to introduce  $V$  because the transformed equation is of an order lower than that of the equation given, we have,

$$\begin{aligned} u &= P_2 \frac{D+2n-2}{D} v \\ &= (D+2n-2)(D+2n-4)\dots(D+2)v \dots\dots(c), \\ 0 &= (D+2n-2)(D+2n-4)\dots(D+2)V. \end{aligned}$$

The latter equation gives for  $V$  the general value,

$$V = c_1 \epsilon^{-2\theta} + c_2 \epsilon^{-4\theta} \dots + c_{n-1} \epsilon^{-(2n-2)\theta},$$

of which it suffices to retain one term. Retaining the first,

substituting in (b), and operating on both sides with  $D + p$ , we get

$$(D + p)v - (D + 2n - 2 - p)\epsilon^{2\theta}v = c_1(p - 2)\epsilon^{-2\theta}.$$

Restoring  $x$ , and integrating, a value of  $v$  is found, involving two arbitrary constants, whence  $u$  will be given by

$$u = \left(x \frac{d}{dx} + 2n - 2\right) \left(x \frac{d}{dx} + 2n - 4\right) \dots \left(x \frac{d}{dx} + 2\right) v \dots (d).$$

The proposed equation is also integrable when  $p$  is an odd integer, and when  $2n - p$  is an even integer. In the former case we may assume as the transformed equation,

$$v - \frac{(D + 2n - 1 - p)(D + 2n - 1 - p - 1)}{(D + p)(D + p - 1)} \epsilon^{2\theta}v = 0,$$

which must be integrated by Prop. I. In the latter case we must assume

$$v - \epsilon^{2\theta}v = V;$$

but in this case two constants must be retained in  $V$ ; viz. one from each set of the reducing operations by which the factors of  $\phi(D)$  are made to disappear.

6. It will be observed that, in the foregoing examples, we reduce the proposed symbolical equation by Propositions II. and III, either directly to an equation of the first order, or to a form which by Prop. I. is resolvable into a system of equations of the first order. But there exist other equations admitting of finite solution; for example such as by Props. II. and III. are reducible to either of the primary forms,

$$v + \frac{a(D - 2)^2 \pm n^2}{D(D - 1)} \epsilon^{2\theta}v = 0 \dots \dots \dots (13),$$

$$v + \frac{(D - 1)(D - 2)}{aD^2 \pm n^2} \epsilon^{2\theta}v = 0 \dots \dots \dots (14).$$

The former of these is the symbolical form of the equation

$$(1 + ax^2) \frac{d^2u}{dx^2} + ax \frac{du}{dx} \pm n^2u = 0,$$

which is reducible to  $\frac{d^2u}{dt^2} \pm n^2u = 0$ , by the assumption

$$t = \int \frac{dx}{\sqrt{(1+ax^2)}}.$$

The latter is the symbolical form of the equation

$$(x^2 + a)x^2 \frac{d^2u}{dx^2} + (2x^2 + a)x \frac{du}{dx} \pm n^2u = 0,$$

which is reducible to  $\frac{d^2u}{dt^2} \pm n^2u = 0$ , by the assumption

$$t = \int \frac{dx}{x\sqrt{(x^2+a)}}.$$

Hence, the ordinary solutions of (13) and (14) will be obtained by substituting

$$t = \int \frac{dx}{\sqrt{(1+ax^2)}}, \quad t = \int \frac{dx}{x\sqrt{(x^2+a)}},$$

in the solution of the equation  $\frac{d^2u}{dt^2} \pm n^2u = 0$ .

It may be added that the forms (13) and (14) are allied, the one being convertible into the other by changing  $\theta$  to  $-\theta$ .

Ex. 11. Given

$$(1-x^2) \frac{d^2u}{dx^2} - (2m+1)x \frac{du}{dx} + (q^2-m^2)u = 0.$$

The symbolical form is

$$u - \frac{(D+m-2)^2 - q^2}{D(D-1)} \epsilon^{2\theta} u = 0.$$

If we apply Prop. II. so as to convert  $D$  into  $D-m$ , and then by Prop. III. reduce the equation to the general form (13), we shall obtain the final solution in the form

$$u = \left(\frac{d}{dx}\right)^m \{c_1 \cos(q \sin^{-1} x) + c_2 \sin(q \sin^{-1} x)\}.$$

7. *Pfaff's Equation.* The differential equation,

$$(a + bx^n) x^2 \frac{d^2 u}{dx^2} + (c + ex^n) x \frac{du}{dx} + (f + gx^n) u = X \dots (a),$$

which includes all binomial equations of the second order, has been discussed by Euler, and, with greater generality, by Pfaff (*Disquisitiones Analyticae*). We propose to investigate the conditions under which it admits of finite solution.

It suffices for this purpose to consider the case in which  $X = 0$ .

The symbolical form is then

$$u + \frac{b(D-n)(D-n-1) + e(D-n) + g}{aD(D-1) + cD + f} \epsilon^{n\theta} u = 0 \dots (b).$$

If  $n$  is not equal to 2, it is convenient to change the independent variable by assuming  $n\theta = 2\theta'$ , whence

$$\frac{d}{d\theta} = \frac{n}{2} \frac{d}{d\theta'}.$$

So that changing  $n\theta$  into  $2\theta'$ , we must change  $D$  into  $\frac{n}{2} D$ . The result may be expressed in the form,

$$u + \frac{b(D-\alpha_1)(D-\alpha_2)}{a(D-\beta_1)(D-\beta_2)} \epsilon^{2\theta'} u = 0 \dots (c),$$

where  $\alpha_1$  and  $\alpha_2$  are roots of the equation,

$$b\left(\frac{n\alpha}{2} - n\right)\left(\frac{n\alpha}{2} - n - 1\right) + e\left(\frac{n\alpha}{2} - n\right) + g = 0 \dots (d),$$

and  $\beta_1, \beta_2$  are roots of the equation,

$$a \frac{n\beta}{2} \left(\frac{n\beta}{2} - 1\right) + c \frac{n\beta}{2} + f = 0 \dots (e).$$

1st, By Prop. III, (c) can be immediately reduced to the form

$$v + \frac{b(D-\alpha_1)(D-\alpha_1-1)}{a(D-\beta_1)(D-\beta_1-1)} \epsilon^{2\theta'} v = 0,$$

and then resolved into two equations of the first order, if we have at the same time  $\alpha_1 - \alpha_2$ , and  $\beta_1 - \beta_2$  odd integers.

2ndly, The equation can, by Prop. III, be reduced to an equation of the first order if any one of the four quantities

$$\alpha_1 - \beta_1, \quad \alpha_1 - \beta_2, \quad \alpha_2 - \beta_1, \quad \alpha_2 - \beta_2$$

is an even integer.

3rdly, It is easily shewn that by Props. II. and III. (c) is reducible to the integrable form (13) if the quantities

$$\beta_1 - \beta_2 \text{ and } \alpha_1 + \alpha_2 - \beta_1 - \beta_2$$

are both odd integers.

4thly, It is in like manner reducible to (14) if the quantities

$$\alpha_1 - \alpha_2 \text{ and } \alpha_1 + \alpha_2 - \beta_1 - \beta_2$$

are both odd integers.

These results may be collected into the following theorem. The equation (c) is integrable in finite terms, 1st, if any one of the four quantities represented by  $\alpha - \beta$  is an even integer; 2ndly, if any two of the quantities

$$\alpha_1 - \alpha_2, \quad \beta_1 - \beta_2, \quad \alpha_1 + \alpha_2 - \beta_1 - \beta_2$$

are odd integers.

In this theorem the integral values are supposed to be either positive or negative, and the even ones to include the value 0.

The above results are equivalent to those of Pfaff, as presented with some slight increase of generality in a memoir by Sauer (*Crelle*, Vol. II. p. 93). Pfaff's conditions are however exhibited in so complex a form as to render the comparison difficult. His method, it is needless to say, is wholly different from the above.

[See the *Supplementary Volume*, Chapter xxx. Art. 5.]

*Symbolical equations which are not binomial.*

8. Although processes of greater or less generality may be established for the treatment of equations which, when symbolically expressed, involve more than two terms in the first member, yet their reduction if possible by some preliminary transformation to the binomial form should always be our first object. We purpose here to illustrate this observation.

Ex. 12. Given  $\frac{d^2y}{dx^2} = a - \frac{by}{(2cx - x^2)^2}$ .

Writing this equation in the form

$$(2c - x)^2 x^2 \frac{d^2y}{dx^2} + by = a (2cx - x^2)^2,$$

we see at once that its symbolical form will not be binomial. Assuming  $y = (2c - x)^m u$ , we have on reduction

$$(2c - x) x^2 \frac{d^2u}{dx^2} - 2mx^2 \frac{du}{dx} + \frac{m(m-1)x^2 + b}{2c - x} u = \frac{ax^2}{(2c - x)^{m-1}}.$$

Now let  $m$  be so determined as to make the numerator of the third term divisible by its denominator. This involves the condition

$$m(m-1) + \frac{b}{4c^2} = 0 \dots\dots\dots(a),$$

while the differential equation becomes

$$(2c - x) x^2 \frac{d^2u}{dx^2} - 2mx^2 \frac{du}{dx} - m(m-1)(2c + x) u = \frac{ax^2}{(2c - x)^{m-1}},$$

of which the symbolical form is

$$(D-m)(D+m-1)u - \frac{1}{2c}(D+m-1)(D+m-2)\epsilon^\theta u = \frac{a}{2c} \frac{\epsilon^{2\theta}}{(2c - \epsilon^\theta)^{m-1}},$$

whence, operating on both sides with  $(D+m-1)^{-1}$ ,

$$(D-m)u - \frac{1}{2c}(D+m-2)\epsilon^\theta u = \frac{a}{2c} \epsilon^{(1-m)\theta} D^{-1} \epsilon^{(m+1)\theta} (2c - \epsilon^\theta)^{1-m}.$$

Restoring  $x$ , and solving the equation, we have, on representing  $2c - x$  by  $X$ ,

$$u = ax^m X^{1-2m} \int x^{-2m} X^{2m-2} \int x^m X^{1-m} dx^2,$$

which integration by parts reduces to the form

$$u = \frac{a \left\{ x^m X^{1-2m} \int X^m x^{1-m} dx - x^{1-m} \int x^m X^{1-m} dx \right\}}{2c(2m-1)}.$$

$$\text{Therefore } y = \frac{a \left\{ x^m X^{1-m} \int x^{1-m} X^m dx - x^{1-m} X^m \int x^m X^{1-m} dx \right\}}{2c(2m-1)},$$

the integral required. It is to be noted that each integration introduces an arbitrary constant. It is also seen that each value of  $m$  derived from (a) leads to the same result.

The above equation occurs in the problem of determining the tendency of an elastic bridge to break, when a heavy body, e.g. a railway train, passes rapidly over it. The equation between  $y$  and  $x$  is, on a certain hypothesis, that of the trajectory described. See an interesting paper by Prof. Stokes (*Cambridge Phil. Transactions*, Vol. VIII. p. 708).

$$\text{Ex. 13. Given } (1 - \mu^2) \frac{d}{d\mu} (1 - \mu^2) \frac{du}{d\mu} + n(n+1)(1 - \mu^2) u + \frac{d^2 u}{d\phi^2} = 0,$$

the well-known equation of Laplace's functions.

Representing  $\frac{d}{d\phi} \sqrt{-1}$  by  $\alpha$ , the equation may be expressed in the form

$$(1 - \mu^2)^2 \frac{d^2 u}{d\mu^2} - 2\mu(1 - \mu^2) \frac{du}{d\mu} + \{n(n+1)(1 - \mu^2) - \alpha^2\} u = 0,$$

and it is evident that it would not, on assuming  $\mu = \epsilon^\theta$ , take the binomial form.

Let then  $u = (1 - \mu^2)^r v$ . We find, on substitution, and division of the result by  $(1 - \mu^2)^{r+1}$ ,

$$(1-\mu^2) \frac{d^2 v}{d\mu^2} - (4r+2) \mu \frac{dv}{d\mu} + \{n(n+1) - 4r^2 - 2r\} v + \frac{4r^2 - a^2}{1-\mu^2} v = 0 \dots (a).$$

Let  $4r^2 - a^2 = 0$ . Then  $r = \pm \frac{a}{2}$ . Either sign may be taken. Choosing the lower, we have

$$(1-\mu^2) \frac{d^2 v}{d\mu^2} + 2(a-1) \mu \frac{dv}{d\mu} + \{n(n+1) - a(a-1)\} v = 0,$$

an equation which, on making  $\mu = \epsilon^\theta$ , assumes the symbolical form

$$v - \frac{(D-a+n-1)(D-a-n-2)}{D(D-1)} \epsilon^{2\theta} v = 0 \dots \dots \dots (b).$$

To integrate this, assume

$$w - \frac{(D-a-n-1)(D-a-n-2)}{D(D-1)} \epsilon^{2\theta} w = 0 \dots \dots \dots (c).$$

Then by Prop. III.,

$$\begin{aligned} v &= (D-a+n-1)(D-a+n-3) \dots (D-a-n+1) w \\ &= \mu^{n+a} \left( \frac{d}{d\mu} \frac{1}{\mu} \right)^n \mu^{n-a} w \dots \dots \dots (d), \end{aligned}$$

while (c), resolved by Prop. I. and integrated, gives the solution

$$w = (1+\mu)^{n+a} \psi(\phi) + (1-\mu)^{n+a} \chi(\phi) \dots \dots \dots (e),$$

$\psi$  and  $\chi$  being arbitrary functional signs. This expression for  $w$  having been substituted in (d), we must write  $\frac{d}{d\phi} \sqrt{(-1)}$  for  $a$ , and interpret the result.

Now if, instead of  $\psi(\phi)$  and  $\chi(\phi)$ , we write  $\psi\{\epsilon^{\phi\sqrt{(-1)}}\}$  and  $\chi\{\epsilon^{\phi\sqrt{(-1)}}\}$ , as we are evidently permitted to do, and if we observe that generally

$$\begin{aligned}
t^{\frac{d}{d\phi}\sqrt{(-1)}} f\{\epsilon^{\phi\sqrt{(-1)}}\} &= \epsilon^{\log t \frac{d}{d\phi}\sqrt{(-1)}} f\{\epsilon^{\phi\sqrt{(-1)}}\} \\
&= f[\epsilon^{\{\phi + \log t \sqrt{(-1)}\}\sqrt{(-1)}}] = f\{\epsilon^{\phi\sqrt{(-1)} - \log t}\} \\
&= f\left\{\frac{\epsilon^{\phi\sqrt{(-1)}}}{t}\right\} \dots\dots\dots (f),
\end{aligned}$$

we shall ultimately find

$$u = F\left\{\mu, \frac{\sqrt{(1-\mu^2)}}{\mu} \epsilon^{\phi\sqrt{(-1)}}\right\},$$

$$\begin{aligned}
\text{where } F\{\mu, \epsilon^{\phi\sqrt{(-1)}}\} &= \mu^n \left(\frac{d}{d\mu} \frac{1}{\mu}\right)^n \left\{(\mu + \mu^2)^n \psi\left(\frac{\mu \epsilon^{\phi\sqrt{(-1)}}}{1 + \mu}\right) \right. \\
&\quad \left. + (\mu - \mu^2)^n \chi\left(\frac{\mu \epsilon^{\phi\sqrt{(-1)}}}{1 - \mu}\right)\right\} \dots\dots\dots (15),
\end{aligned}$$

which is the complete integral.

For a discussion of this result, and for the finite expression for Laplace's functions to which it leads, the reader is referred to a paper on the Equation of Laplace's functions in the *Cambridge Mathematical Journal*. (New Series, Vol. I. p. 10.)

If in the equation (a) we make the third instead of the fourth term to vanish, which gives for  $r$  the values  $\frac{n}{2}$  and  $-\frac{n+1}{2}$ , and then assume  $\frac{\mu}{\sqrt{(1-\mu^2)}} = t$ , we shall obtain, taking the second value of  $r$ , the symbolical equation

$$v + \frac{(D+n-1)^2 - a^2}{D(D-1)} \epsilon^{2\theta} v = 0.$$

Now by Propositions II. and III. this is reducible to the integrable form

$$w + \frac{(D-2)^2 - a^2}{D(D-1)} \epsilon^{2\theta} w = 0,$$

by the relation

$$v = \epsilon^{-(n+1)\theta} D(D-1) \dots (D-n) w \\ = \left(\frac{d}{dt}\right)^{n+1} w.$$

Hence we find

$$v = \left(\frac{d}{dt}\right)^{n+1} [c_1 \{t + \sqrt{(1+t^2)}\}^a + c_2 \{t + \sqrt{(1+t^2)}\}^{-a}],$$

whence  $u$  is known.

Let us examine the form of the solution, when, as is common in the expression of Laplace's equation, we replace  $\mu$  by  $\cos \theta$ . We find

$$t = \cot \theta, \quad \frac{d}{dt} = -\sin^2 \theta \frac{d}{d\theta},$$

whence  $t + \sqrt{(1+t^2)} = \cot \frac{1}{2} \theta$ .

Substituting, and observing that  $u = (\sin \theta)^{-n-1} v$ , we have

$$u = (\sin \theta)^{-n-1} \left(\sin^2 \theta \frac{d}{d\theta}\right)^{n+1} \left\{ c_1 \left(\cot \frac{\theta}{2}\right)^a + c_2 \left(\tan \frac{\theta}{2}\right)^a \right\}.$$

And hence, restoring to  $a$  its meaning, introducing arbitrary functions for constants, and effecting one of the differentiations, we may deduce the following solution of Laplace's equation, viz.:

$$u = (\sin \theta)^{-n} \left(\sin \theta \frac{d}{d\theta} \sin \theta\right)^n \left[ F_1 \left\{ \epsilon^{\phi \sqrt{(-1)}} \tan \frac{\theta}{2} \right\} \right. \\ \left. + F_2 \left\{ \epsilon^{-\phi \sqrt{(-1)}} \tan \frac{\theta}{2} \right\} \right] \dots \dots (16).$$

Under this singularly elegant form the solution, obtained by a different method, was given by Professor Donkin. (*Philosophical Transactions*, for 1857.)

*Solution of linear equations by series.*

9. PROP. IV. *If a linear differential equation whose second member is 0 be reduced to the symbolical form*

$$f_0(D)u + f_1(D)\epsilon^\theta u + f_2(D)\epsilon^{2\theta}u \dots + f_n(D)\epsilon^{n\theta}u = 0 \dots (17)$$

(Art. 1), then a particular solution will be

$$u = \sum u_m \epsilon^{m\theta} \dots \dots \dots (18),$$

the value of the index  $m$  in the first term being any root of the equation  $f_0(m) = 0$ , the corresponding value of  $u_m$  an arbitrary constant, and the law of the succeeding constants being expressed by the equation

$$f_0(m)u_m + f_1(m)u_{m-1} + f_2(m)u_{m-2} \dots + f_n(m)u_{m-n} = 0 \dots (19).$$

For the form of  $u$  assigned in (18) will constitute a solution of (17) if, on substituting that form for  $u$  in the first member of (17) and arranging the result in ascending powers of  $\epsilon^\theta$ , each coefficient should vanish. And this, as we shall see, will take place if the coefficients are subject to the relation expressed by (19).

Assuming then  $u = \sum u_m \epsilon^{m\theta}$ , we find,

$$f_0(D)u = \sum f_0(D)u_m \epsilon^{m\theta} = \sum f_0(m)u_m \epsilon^{m\theta}, \text{ by (2),}$$

$$f_1(D)\epsilon^\theta u = \sum f_1(m+1)u_m \epsilon^{(m+1)\theta},$$

$$f_2(D)\epsilon^{2\theta}u = \sum f_2(m+2)u_m \epsilon^{(m+2)\theta},$$

and so on. In the first of these, we see that the coefficient of any particular term  $\epsilon^{m\theta}$  is  $f_0(m)u_m$ . In the second, the coefficient of  $\epsilon^{(m+1)\theta}$  is  $f_1(m+1)u_m$ , and therefore the coefficient of  $\epsilon^{m\theta}$  is  $f_1(m)u_{m-1}$ . In the third, the coefficient of  $\epsilon^{m\theta}$  is  $f_2(m)u_{m-2}$ ; and so on. Thus the aggregate coefficient of  $\epsilon^{m\theta}$  is

$$f_0(m)u_m + f_1(m)u_{m-1} + f_2(m)u_{m-2} \dots + f_n(m)u_{m-n},$$

and this, equated to 0, expresses the law (19).

Let  $u_r \epsilon^{r\theta}$  be the first term in the developed value of  $u$ ; then must we suppose  $u_{r-1} = 0$ ,  $u_{r-2} = 0$ , &c. and (19) becomes

$$f_0(r) u_r = 0.$$

As, by hypothesis,  $u_r$  is not equal to 0, this gives  $f_0(r) = 0$ , for the determination of  $r$ , and leaves  $u_r$  arbitrary. Hence the proposition is established.

Thus there will, except in particular cases of failure hereafter to be considered, be as many distinct solutions of the form (18), each involving an arbitrary constant, as there are units in the degree of  $f_0(m)$ .

Ex. 14. Given  $\frac{d^2 u}{dx^2} - \frac{a-1}{x} \frac{du}{dx} - n^2 u = 0$ .

The symbolical form is

$$D(D-a)u - n^2 \epsilon^{2\theta} u = 0.$$

Hence, we have  $u = \sum u_m x^m$ , the law of formation of the coefficients being

$$m(m-a)u_m - n^2 u_{m-2} = 0, \text{ or } u_m = \frac{n^2}{m(m-a)} u_{m-2},$$

while the initial exponent is 0 or  $a$ . There are therefore two ascending series, one beginning with  $C$ , the other with  $C'x^a$ . Thus we have

$$\begin{aligned} u = & C + \frac{Cn^2}{2(2-a)}x^2 + \frac{Cn^4}{2 \cdot 4(2-a)(4-a)}x^4 + \&c. \\ & + C'x^a + \frac{C'n^2x^{a+2}}{2(a+2)} + \frac{C'n^4x^{a+4}}{2 \cdot 4(a+4)(a+2)} + \&c. \end{aligned}$$

10. When the equation  $f_0(m) = 0$ , has equal or imaginary roots, the following procedure must be adopted. Let the solution of the equation  $f_0(D)u = 0$ , be

$$u = AP + BQ + CR + \&c. \dots\dots\dots(20),$$

$A, B, C$ , &c. being the arbitrary constants. Substitute this

value in the given differential equation, regarding  $A, B, C$ , &c. as variable, and the result will assume the form

$$A'P + B'Q + C'R + \&c. = 0 \dots\dots\dots (21),$$

and will be satisfied if we have

$$A' = 0, \quad B' = 0, \quad C' = 0, \quad \&c. \dots\dots\dots (22).$$

This will indeed become a system of linear simultaneous equations for determining  $A, B, C$ , &c. And the solution of this system in a series will be of the form

$$A = \Sigma a_m \epsilon^{m\theta}, \quad B = \Sigma b_m \epsilon^{m\theta}, \quad C = \Sigma c_m \epsilon^{m\theta}, \quad \&c.$$

the law of formation of the coefficients  $a_m, b_m, c_m$ , &c. being expressed by a system of simultaneous equations formed from (22), by changing therein every term of the form  $\phi(D)\epsilon^{i\theta}A$  into  $\phi(m)a_{m-i}$ , &c. (*Philosophical Transactions*.)

There is a particular case of exception to the above rule. When two of the roots of  $f_0(m) = 0$  differ by a multiple of the common difference of the indices of the ascending development, the equation  $f_0(D) = 0$ , must be replaced by what that equation would become were the roots in question equal.

Ex. 15. Given  $\frac{d^2u}{dx^2} + \frac{1}{x} \frac{du}{dx} + q^2u = 0$ .

The symbolical form is

$$D^2u + q^2\epsilon^{2\theta}u = 0 \dots\dots\dots (a).$$

Now  $D^2u = 0$  gives  $u = A + B\theta$ . Substituting this value in (a), regarding  $A$  and  $B$  as variable, we have

$$D^2A + q^2\epsilon^{2\theta}A + 2DB + \theta(D^2B + q^2\epsilon^{2\theta}B) = 0,$$

which furnishes the two equations,

$$D^2A + q^2\epsilon^{2\theta}A + 2DB = 0, \quad D^2B + q^2\epsilon^{2\theta}B = 0,$$

whence  $A = \Sigma a_m \epsilon^{m\theta}$ ,  $B = \Sigma b_m \epsilon^{m\theta}$ , with the relations

$$m^2a_m + q^2a_{m-2} + 2mb_m = 0, \quad m^2b_m + q^2b_{m-2} = 0,$$

from which we have

$$b_m = \frac{-q^2}{m^2} b_{m-2}, \quad a_m = \frac{-q^2}{m^2} a_{m-2} + \frac{2q^2}{m^3} b_{m-2} \dots \dots \dots (b).$$

Thus we find, on substitution, and restoration of  $x$ ,

$$u = a_0 + a_2 x^2 + a_4 x^4 + \&c. \\ + \log x (b_0 + b_2 x^2 + b_4 x^4 + \&c.),$$

where  $a_0, b_0$  are arbitrary, and the succeeding values determined by (b).

Were the symbolical equation of the form

$$D (D \pm 2i) u + q^2 \epsilon^{2\theta} u = 0,$$

it would still be necessary to determine the form of the primary assumption by solving the equation  $D^2 u = 0$ , not by  $D (D \pm 2i) u = 0$ . We should therefore still have  $u = A + B\theta$ , in which  $A$  and  $B$  are series to be determined as before.

Ex. 16. Given  $x^2 \frac{d^2 u}{dx^2} + x \frac{du}{dx} + (n^2 + x^2) u = 0$ .

The symbolical equation is

$$(D^2 + n^2) u + \epsilon^{2\theta} u = 0 \dots \dots \dots (a).$$

Now the equation  $(D^2 + n^2) u = 0$  gives

$$u = A \cos n\theta + B \sin n\theta \dots \dots \dots (b),$$

substituting which in (a), and equating to 0 the coefficients of  $\cos n\theta$  and  $\sin n\theta$  in the result, we have

$$D^2 A + 2nDB + \epsilon^{2\theta} A = 0,$$

$$D^2 B - 2nDA + \epsilon^{2\theta} B = 0,$$

whence  $A = \Sigma a_m \epsilon^{m\theta}$ ,  $B = \Sigma b_m \epsilon^{m\theta}$ , with the relations,

$$m^2 a_m + 2mn b_m + a_{m-2} = 0,$$

$$m^2 b_m - 2mn a_m + b_{m-2} = 0,$$

and therefore,

$$a_m = -\frac{ma_{m-2} - 2nb_{m-2}}{m(m^2 + 4n^2)}, \quad b_m = -\frac{mb_{m-2} + 2na_{m-2}}{m(m^2 + 4n^2)} \dots\dots\dots (c).$$

Thus the solution assumes the form,

$$u = \cos(n \log x) (a_0 + a_2 x^2 + a_4 x^4 + \&c.) \\ + \sin(n \log x) (b_0 + b_2 x^2 + b_4 x^4 + \&c.),$$

wherein  $a_0$  and  $b_0$  are arbitrary, and the succeeding coefficients determined by (c).

The fundamental equation (19), written in a reversed order, determines the law of the formation of the coefficients in those solutions of (17) which are expressible in descending powers of  $x$ . The number of such solutions will be equal to the degree of the equation  $f_n(m) = 0$ , but their respective first exponents will be its roots severally diminished by  $n$ .

For the extension of the above theory to the case in which the given differential equation has a second member  $X$ , the reader is referred to the original memoir.

### *Theory of Series.*

11. The relations which enable us to express the integrals of differential equations in series, enable us also to reduce the summation of series to the solution of differential equations. Thus, from Proposition IV. it appears that if  $u = \Sigma u_m x^m$ , where the law of formation of the successive coefficients, is

$$f_0(m) u_m + f_1(m) u_{m-1} \dots + f_n(m) u_{m-n} = 0 \dots\dots\dots (23),$$

the value of  $u$  will be obtained by the solution of the differential equation

$$f_0(D) u + f_1(D) \epsilon^\theta u \dots + f_n(D) \epsilon^{n\theta} u = 0 \dots\dots\dots (24).$$

We suppose here  $f_0(m), f_1(m) \dots f_n(m)$ , to be polynomials, and that the series is complete; i.e. contains all the terms which can be formed in subjection to its law expressed by (23), the first exponent being therefore a root of  $f_0(m) = 0$ .

When the series is incomplete, the first member of the differential equation will be the same as for the complete series, while the second member will be formed by substituting in the first member, in the place of  $u$ , the series which it represents. It is obvious that all the terms will disappear, except a few derived from that end of the series where the defect of completeness exists, so that the second member of the differential equation will be finite.

Ex. 17. Let

$$u = 1 - \frac{n^2}{1 \cdot 2} x^2 + \frac{n^2 (n^2 - 2^2)}{1 \cdot 2 \cdot 3 \cdot 4} x^4 - \frac{n^2 (n^2 - 2^2) (n^2 - 4^2)}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} x^6, \text{ \&c.}$$

Here  $u = \sum u_m x^m$ , with the relation,

$$u_m = - \frac{n^2 - (m-2)^2}{m(m-1)} u_{m-2}.$$

Or,

$$m(m-1) u_m - \{(m-2)^2 - n^2\} u_{m-2} = 0,$$

and we observe that the series is complete, the first index 0 being a root of  $m(m-1) = 0$ .

Hence, the differential equation will be

$$D(D-1) u - \{(D-2)^2 - n^2\} \epsilon^{2\theta} u = 0,$$

of which the solution, expressed in terms of  $x$ , is

$$u = c_1 \cos(n \sin^{-1} x) + c_2 \sin(n \sin^{-1} x).$$

The constants must be determined by comparison with the original series. We thus find  $c_1 = 1$ ,  $c_2 = 0$ .

The following is a species of application which is of frequent use in the theory of probabilities.

Ex. 18. The series

$$p^a \left\{ 1 + aq + \frac{a(a+1)}{1 \cdot 2} q^2 \dots + \frac{a(a+1) \dots (a+b-1)}{1 \cdot 2 \dots b} q^b \right\},$$

occurs as the expression of the probability that an event whose probability of occurrence in a single trial is  $p$ , and of failure  $q$ , will occur at least  $a$  times in  $a + b$  trials.

Representing the series within the brackets by  $u$ , and assuming  $q = \epsilon^\theta$ , we have  $u = \sum u_m \epsilon^{m\theta}$ , where

$$mu_m - (m + a - 1) u_{m-1} = 0.$$

Hence, we shall have

$$Du - (D + a - 1) \epsilon^\theta u = - \frac{a(a+1) \dots (a+b)}{1 \cdot 2 \dots b} \epsilon^{(b+1)\theta},$$

or, restoring  $q$ ,

$$\frac{du}{dq} - \frac{a}{1-q} u = - \frac{a(a+1) \dots (a+b)}{1 \cdot 2 \dots b} \frac{q^b}{1-q}.$$

Integrating which, we have

$$u = (1-q)^{-a} \left\{ C - \frac{a(a+1) \dots (a+b)}{1 \cdot 2 \dots b} \int_0^q q^b (1-q)^{a-1} dq \right\}.$$

Now the first term of the development of this expression in ascending powers of  $q$  will be  $C$ ; whence, comparing with the bracketed series, we have  $C = 1$ . Substituting, and observing that  $p = 1 - q$ , the expression for the probability in question becomes

$$1 - \frac{a(a+1) \dots (a+b)}{1 \cdot 2 \dots b} \int_0^q q^b (1-q)^{a-1} dq \dots \dots \dots (a).$$

To this we may however give a more symmetrical form. For

$$\begin{aligned} \int_0^q q^b (1-q)^{a-1} dq &= \left( \int_0^1 - \int_q^1 \right) q^b (1-q)^{a-1} dq \\ &= \frac{\Gamma(b+1) \Gamma(a)}{\Gamma(a+b+1)} - \int_q^1 q^b (1-q)^{a-1} dq, \end{aligned}$$

by a known theorem of definite integration.

Substituting in (a), and observing that

$$\frac{a(a+1) \dots (a+b)}{1 \cdot 2 \dots b} = \frac{\Gamma(a+b+1)}{\Gamma(b+1) \Gamma(a)},$$

we find

$$\text{Probability} = \frac{\Gamma(a+b+1)}{\Gamma(a)\Gamma(b+1)} \int_0^1 q^b (1-q)^{a-1} dq,$$

or, as it may be otherwise expressed,

$$\text{Probability} = \frac{\int_0^1 q^b (1-q)^{a-1} dq}{\int_0^1 q^b (1-q)^{a-1} dq} \dots\dots\dots(b).$$

The peculiar advantage of this form of expression is that, precisely in those cases in which the series becomes unmanageable from the largeness of  $a$  and  $b$ , the integrals admit, as Laplace has shewn, of a rapid approximation (*Théorie Analytique des Probabilités*).

Ex. 19. The function  $(1 - 2\nu \cos \omega + \nu^2)^{-n}$  being expanded in a series of the form  $A_0 + 2(A_1 \cos \omega + A_2 \cos 2\omega \dots + \&c.)$ , it is required to determine  $A_r$ .

We have

$$(1 - 2\nu \cos \omega + \nu^2)^{-n} = \{1 - \nu \epsilon^{\omega \sqrt{(-1)}}\}^{-n} \times \{1 - \nu \epsilon^{-\omega \sqrt{(-1)}}\}^{-n}.$$

Expanding each factor, and seeking the common coefficient of  $\epsilon^{r\omega \sqrt{(-1)}}$  and  $\epsilon^{-r\omega \sqrt{(-1)}}$  in the product, we find, putting  $t = \nu^2$ ,

$$A_r = t^{\frac{r}{2}} \sum_{m=0}^{m=\infty} u_m t^m,$$

where generally,

$$m(m+r)u_m - (m+n-1)(m+n+r-1)u_{m-1} = 0,$$

$$\text{while } u_0 = \frac{n(n+1) \dots (n+r-1)}{1 \cdot 2 \dots r}.$$

Hence the differential equation will be

$$D(D+r)u - (D+n-1)(D+n+r-1)\epsilon^\theta u = 0,$$

or,

$$u - \frac{(D+n-1)(D+n+r-1)}{D(D+r)} \epsilon^\theta u = 0.$$

Now this can, by Prop. III, be reduced to the form,

$$v - \epsilon^\theta v = V,$$

by the relations,

$$u = (D + n - 1) \dots (D + 1) (D + n + r - 1) \dots (D + r + 1) v,$$

$$V = \{(D + n - 1) \dots (D + 1) (D + n + r - 1) \dots (D + r + 1)\}^{-1} U.$$

In determining  $V$  from the latter equation, it suffices to introduce two arbitrary constants, one from each of the two sets of inverse operations. The final solution, in the obtaining of which the only difficulty consists in the reductions, is

$$A_r = \frac{1}{\Gamma(n)} t^{\frac{r}{2}} \left( \frac{d}{dt} \right)^{n-1} \frac{t^{r+n-1}}{(1-t)^n}.$$

12. When, in the series  $\sum u_m x^m$ , the coefficient  $u_m$  is a rational function of  $m$  invariable in form, the summation is most readily effected in the following manner.

Let the series be  $\sum \phi(m) x^m$ ; then putting  $x = \epsilon^\theta$ ,

$$\begin{aligned} u &= \sum \phi(m) \epsilon^{m\theta} = \sum \phi(D) \epsilon^{m\theta} \\ &= \phi(D) \sum \epsilon^{m\theta} \dots\dots\dots (25). \end{aligned}$$

Hence, if the summation is from  $m = 0$  to  $m = \text{infinity}$ , we have

$$u = \phi(D) \frac{1}{1 - \epsilon^\theta};$$

but if the summation is from  $m = a$  to  $m = b$  inclusive,

$$u = \phi(D) \frac{\epsilon^{a\theta} - \epsilon^{(b+1)\theta}}{1 - \epsilon^\theta}.$$

Ex. 20. Let  $u = \frac{4x^3}{1 \cdot 2 \cdot 3} + \frac{5x^4}{2 \cdot 3 \cdot 4} + \frac{6x^5}{3 \cdot 4 \cdot 5} + \&c.$

$$\text{Here } \phi(m) = \frac{m+1}{m(m-1)(m-2)};$$

$$\text{therefore } u = \frac{D+1}{D(D-1)(D-2)} (\epsilon^{3\theta} + \epsilon^{4\theta} + \&c.)$$

$$= \left\{ \frac{1}{2} D^{-1} - 2(D-1)^{-1} + \frac{3}{2}(D-2)^{-1} \right\} \frac{\epsilon^{3\theta}}{1 - \epsilon^\theta}.$$

The final result is

$$u = \frac{7x^2}{4} - \frac{x}{2} - \left(\frac{1}{2} - 2x + \frac{3}{2}x^2\right) \log(1-x).$$

*Generalization of the foregoing theory.*

13. As Propositions I, II, III. are founded solely on the particular law of combination of the symbols  $D$  and  $\epsilon^\theta$ , expressed by the equation

$$f(D) \epsilon^{m\theta} u = \epsilon^{m\theta} f(D+m) u,$$

they remain true for any symbols  $\pi$  and  $\rho$ , whatever their interpretation, which combine according to the same formal law; viz.

$$f(\pi) \rho^m u = \rho^m f(\pi+m) u \dots\dots\dots(26).$$

Thus, supposing the law obeyed, the symbolical equation,

$$u + \phi(\pi) \rho^n u = U \dots\dots\dots(27),$$

can, by Prop. III. considered in its purely formal character, be transformed into

$$v + \psi(\pi) \rho^n v = V \dots\dots\dots(28),$$

by the assumption,

$$u = P_n \frac{\phi(\pi)}{\psi(\pi)} v, \quad U = P_n \frac{\phi(\pi)}{\psi(\pi)} V.$$

The corresponding transformations flowing from Propositions I. and II, it is unnecessary to state.

Now the law (26) is obeyed, not alone by the pure symbols  $D$  and  $\epsilon^\theta$ , but by certain combinations of those symbols. Thus, if we assume

$$\pi = D - n\phi(D) \epsilon^\theta, \quad \rho = \phi(D) \epsilon^\theta$$

the law will still be obeyed. And the importance of the remark consists in this, that an equation which, when expressed by means of the symbols  $D$  and  $\epsilon^\theta$ , is not a binomial, may assume the binomial form for some other determination of  $\pi$  and  $\rho$ .

If in (26), we make  $m = 1$ , we have  $f(\pi) \rho u = \rho f(\pi + 1) u$ , which shews that  $\rho$  may be transferred from the right to the left of  $f(\pi)$ , if we, so to speak, add to  $\pi$  the constant increment 1. This then suggests the more general law,

$$f(\pi) \rho u = \rho f(\pi + \Delta\pi) u \dots\dots\dots(29),$$

where  $\Delta\pi$  represents any constant quantity regarded as an increment of  $\pi$ . In connexion with this theory, the following proposition is important.

**PROP.** *Supposing  $f(x)$  to represent a function which admits of expansion in ascending positive and integral powers of  $x$ , it is required to developpe  $f(\pi + \rho)$  in ascending powers of  $\rho$ ,  $\pi$  and  $\rho$  being symbols which combine in subjection to the law (29).*

By successive applications of (29) we have,  $m$  being a positive integer,

$$f(\pi) \rho^m u = \rho^m f(\pi + m\Delta\pi) u \dots\dots\dots(30),$$

of which another form is  $\rho^m f(\pi) u = f(\pi - m\Delta\pi) \rho^m u$ . Again, since  $f(\pi + \rho)$  is, by hypothesis, expressible in a series of the form

$$A_0 + A_1 (\pi + \rho) + A_2 (\pi + \rho)^2 + \&c.,$$

we shall have

$$(\pi + \rho) f(\pi + \rho) = f(\pi + \rho) (\pi + \rho) \dots\dots\dots(31),$$

for either member becomes, on substituting for  $f(\pi + \rho)$  the above form,

$$A_0 (\pi + \rho) + A_1 (\pi + \rho)^2 + \&c.$$

Now, let the form of the unknown and sought expansion of  $f(\pi + \rho)$  in ascending powers of  $\rho$ , be

$$\begin{aligned} f(\pi + \rho) &= f_0(\pi) + f_1(\pi) \rho + f_2(\pi) \rho^2 + \&c. \dots\dots(32), \\ &= \Sigma f_m(\pi) \rho^m, \end{aligned}$$

the subject  $u$  being understood though not expressed.

Then, by (31),

$$(\pi + \rho) \Sigma f_m(\pi) \rho^m = \Sigma f_m(\pi) \rho^m (\pi + \rho).$$

But

$$\begin{aligned}(\pi + \rho) \Sigma f_m(\pi) \rho^m &= \Sigma \pi f_m(\pi) \rho^m + \Sigma \rho f_m(\pi) \rho^m \\ &= \Sigma \pi f_m(\pi) \rho^m + \Sigma f_m(\pi - \Delta\pi) \rho^{m+1},\end{aligned}$$

in which the coefficient of  $\rho^m$  is

$$\pi f_m(\pi) + f_{m-1}(\pi - \Delta\pi) \dots \dots \dots (33).$$

Again,

$$\begin{aligned}\Sigma f_m(\pi) \rho^m (\pi + \rho) &= \Sigma f_m(\pi) \rho^m \pi + \Sigma f_m(\pi) \rho^{m+1} \\ &= \Sigma f_m(\pi) (\pi - m\Delta\pi) \rho^m + \Sigma f_m(\pi) \rho^{m+1},\end{aligned}$$

in which the aggregate coefficient of  $\rho^m$  is

$$f_m(\pi) (\pi - m\Delta\pi) + f_{m-1}(\pi).$$

Equating this with (33), we have

$$\pi f_m(\pi) + f_{m-1}(\pi - \Delta\pi) = (\pi - m\Delta\pi) f_m(\pi) + f_{m-1}(\pi),$$

whence

$$\begin{aligned}f_m(\pi) &= \frac{1}{m} \frac{f_{m-1}(\pi) - f_{m-1}(\pi - \Delta\pi)}{\Delta\pi} \\ &= \frac{1}{m} \frac{\Delta f_{m-1}(\pi)}{\Delta\pi} \dots \dots \dots (34),\end{aligned}$$

if we define  $\Delta f(\pi)$ , not, as is usual, by  $f(\pi + \Delta\pi) - f(\pi)$ , but by  $f(\pi) - f(\pi - \Delta\pi)$ . The above equation determines the law of derivation of the coefficients  $f_1(\pi)$ ,  $f_2(\pi)$ , &c. It only remains to determine  $f_0(\pi)$ .

That  $f_0(\pi) = f(\pi)$  may be shewn by induction from the particular cases in which

$$f(\pi + \rho) = \pi + \rho, \quad (\pi + \rho)^2, \quad \&c.$$

or, with more formal propriety, thus :

Let  $\rho_1 = n\rho$ , where  $n$  is a constant,

$$\begin{aligned}f(\pi) \rho_1 &= f(\pi) n\rho = nf(\pi) \rho \\ &= n\rho f(\pi - \Delta\pi) \\ &= \rho_1 f(\pi - \Delta\pi).\end{aligned}$$

Comparing the first and last members, we see that  $\pi$  and  $\rho_1$  combine according to the same law as  $\pi$  and  $\rho$ .

Thus we have

$$f(\pi + \rho_1) = f_0(\pi) + f_1(\pi) \rho_1 + f_2(\pi) \rho_1^2 + \&c.,$$

$f_0(\pi), f_1(\pi), \&c.$  being the same as in (32).

Or,

$$f(\pi + n\rho) = f_0(\pi) + f_1(\pi) n\rho + f_2(\pi) n^2\rho^2 + \&c.;$$

so that, making  $n = 0$ , we have  $f_0(\pi) = f(\pi)$ .

Determining then the successive coefficients by (34), we have finally,

$$\begin{aligned} f(\pi + \rho) = f(\pi) + \frac{\Delta f(\pi)}{\Delta\pi} \rho + \frac{1}{1 \cdot 2} \frac{\Delta^2 f(\pi)}{(\Delta\pi)^2} \rho^2 \\ + \frac{1}{1 \cdot 2 \cdot 3} \frac{\Delta^3 f(\pi)}{(\Delta\pi)^3} \rho^3 + \&c. \dots\dots\dots (35), \end{aligned}$$

wherein it is to be remembered, that

$$\frac{\Delta f(\pi)}{\Delta\pi} = \frac{f(\pi) - f(\pi - \Delta\pi)}{\Delta\pi}.$$

When  $\Delta\pi = 0$ , the symbols  $\pi$  and  $\rho$  become commutative, and (35) assumes the form of Taylor's theorem.

As a particular application of the above, suppose that we have given the trinomial equation

$$(D^2 + aD + b)u + (cD + e)\epsilon^\theta u + f\epsilon^{2\theta}u = 0 \dots\dots (a),$$

and that we desire to ascertain whether this can be transformed into a binomial equation by assuming

$$\pi = D - m\epsilon^\theta, \quad \rho = \epsilon^\theta,$$

assumptions which satisfy the law

$$f(\pi) \rho = \rho f(\pi + 1).$$

Here we have

$$D = \pi + m\rho,$$

whence

$$f(D) = f(\pi) + \frac{\Delta f(\pi)}{\Delta\pi} m\rho + \frac{1}{2} \frac{\Delta^2 f(\pi)}{\Delta\pi^2} m^2\rho^2 + \&c.,$$

where  $\Delta\pi = 1$ , and

$$\frac{\Delta f(\pi)}{\Delta\pi} = f(\pi) - f(\pi - 1).$$

Hence 
$$D^2 + aD + b = \pi^2 + a\pi + b + (2\pi - 1 + a)m\rho + m^2\rho^2,$$
  

$$cD + e = c\pi + e + cm\rho.$$

Thus (a) becomes

$$\{\pi^2 + a\pi + b + (2\pi - 1 + a)m\rho + m^2\rho^2\}u \\ + (c\pi + e + cm\rho)\rho u + f\rho^2u = 0,$$

or  $\pi^2 + a\pi + b + \{(2m + c)\pi + m(a - 1) + e\}\rho + (m^2 + cm + f)\rho^2 = 0,$

and this reduces to a binomial equation, 1st, if  $m$  be a root of the quadratic equation

$$m^2 + cm + f = 0;$$

2ndly, if it be possible to satisfy simultaneously the equations

$$2m + c = 0, \quad m(a - 1) + e = 0,$$

equations which imply the condition

$$2e - c(a - 1) = 0.$$

The discussion of the binomial equation when obtained involves no difficulty.

For a discussion of the general trinomial equation of the second degree, the reader is referred to the original Memoir.

*Laplace's transformation of partial differential equations.*

14. Laplace has developed a method for the reduction of the partial differential equation

$$Rr + Ss + Tt + Pp + Qq + Zz = U \dots\dots (36),$$

$R, S, T, \dots U$  being functions of  $x$  and  $y$ , which is deserving of attention from its great generality.

One of the auxiliary equations in Monge's method is

$$Rdy^2 - Sdx dy + Tdx^2 = 0.$$

Let two integrals of this equation be

$$\phi(x, y) = c, \quad \psi(x, y) = c',$$

and assume two new variables,  $\xi$  and  $\eta$ , connected with  $x$  and  $y$  by the equations

$$\xi = \phi(x, y), \quad \eta = \psi(x, y).$$

The student will have no difficulty in proving that the given equation will assume the form

$$\frac{d^2 z}{d\xi d\eta} + L \frac{dz}{d\xi} + M \frac{dz}{d\eta} + Nz = V \dots \dots \dots (37),$$

$L, M, N, V$  being functions of  $\xi$  and  $\eta$ . The theory of the reduction of this equation is then contained in the following propositions :

1st, The equation (37) may be presented in the form

$$\left(\frac{d}{d\xi} + M\right) \left(\frac{d}{d\eta} + L\right) z + \left(N - LM - \frac{dL}{d\xi}\right) z = V \dots (38).$$

Hence, if the condition

$$N - LM - \frac{dL}{d\xi} = 0 \dots \dots \dots (39)$$

be satisfied, and we assume  $\left(\frac{d}{d\eta} + L\right) z = z'$ , we shall have

$$\left(\frac{d}{d\xi} + M\right) z' = V.$$

The solution of the given equation is then dependent on that of two partial differential equations of the first order.

2ndly, Inverting the order of the symbolic factors, the equation is also solvable if we have

$$N - LM - \frac{dM}{d\eta} = 0 \dots \dots \dots (40).$$

3rdly, The equation (37) can be transformed into a series of other equations of the same form, and therefore integrated, if, for any of those equations, the condition (39) or (40) is satisfied.

For, expressing it in the form (38), let, as before,

$$\left(\frac{d}{d\eta} + L\right) z = z' \dots \dots \dots (41).$$

Then  $\left(\frac{d}{d\xi} + M\right) z' + \left(N - LM - \frac{dL}{d\xi}\right) z = V,$

whence 
$$z = \frac{-\frac{dz'}{d\xi} - Mz' + V}{N - LM - \frac{dL}{d\xi}},$$

which is of the form

$$z = A \frac{dz'}{d\xi} + Bz' + C,$$

$A, B, C$  being functions of  $\xi$  and  $\eta$ . Substituting this expression for  $z$  in (41), we have a result of the form

$$\frac{d^2 z'}{d\xi d\eta} + L' \frac{dz'}{d\xi} + M' \frac{dz'}{d\eta} + N' z' = V' \dots \dots \dots (42).$$

Thus the form (37) is reproduced, but with changed coefficients. Hence the equation is integrable if either of the following conditions is satisfied, viz.

$$N' - L'M' - \frac{dL'}{d\xi} = 0, \quad N' - L'M' - \frac{dM'}{d\eta} = 0 \dots \dots (43).$$

If neither be satisfied, the process of transformation may be indefinitely repeated, and should an equation be obtained in which either of the relations (43) is satisfied, the solution may be found. It has indeed been asserted that "if the given equation be integrable, we shall finally get an equation in which this essential condition is satisfied" (Peacock's *Examples*, p. 464). The state of our knowledge of the conditions of finite integration does not however warrant this confidence.

A discussion of the equation

$$a \frac{d^2 z}{dx^2} + b \frac{d^2 z}{dx dy} + c \frac{d^2 z}{dy^2} + \frac{e \frac{dz}{dx} + f \frac{dz}{dy}}{hx + ky} + \frac{gz}{(hx + ky)^2} = M \dots (a)$$

by Laplace's method is given in Lacroix (Tom. II. pp. 611—614), but it is far too long and too complex to find a place here. The best mode of treating the equation is probably the following. Let  $s$  and  $t$  be two new variables connected with  $x$  and  $y$  by the *linear* relations

$$hx + ky = s, \quad y + mx = t,$$

of which one is suggested by the form of the given equation, while the other is adopted in order to put us in possession of a disposable constant  $m$ . Transforming, and making in the result  $s = \epsilon^\theta$ , we obtain the symbolical equation

$$\{AD(D-1) + ED + g\}z + \frac{d}{dt}\{B(D-1) + F\}\epsilon^\theta z + C\frac{d^2}{dt^2}\epsilon^{2\theta}z = \epsilon^{2\theta}M \dots (b),$$

in which

$$A = ah^2 + bhk + ck^2, \quad B = 2ahm + b(h + km) + 2ck, \\ C = am^2 + bm + c, \quad E = eh + fk, \quad F = em + f.$$

The equation will be a binomial one, if  $m$  be determined so as to make  $C = 0$ . We have then

$$am^2 + bm + c = 0,$$

while the symbolical equation (b) becomes

$$z + \frac{d}{dt} \frac{B(D-1) + F}{AD(D-1) + ED + g} \epsilon^\theta z = \{AD(D-1) + ED + g\}^{-1} \epsilon^{2\theta} M,$$

and is integrable if the following condition is satisfied, viz.

$$\frac{B - F}{B} - \frac{A - E \pm \sqrt{(A - E)^2 - 4g}}{2A} = \text{an integer or 0.}$$

This condition will be found to include the one to which Laplace's method leads.

At the same time it is seen that the equation (b) assumes the binomial form under other conditions than the above; e.g. if we have simultaneously

$$B = 0, \quad F = 0,$$

from which, by elimination of  $m$ , we find

$$f(2ah + bk) - e(bh + 2ck) = 0.$$

This condition being satisfied, and  $m$  determined, the symbolical equation becomes

$$z + C \frac{d^2}{dt^2} \frac{1}{AD(D-1) + ED + g} \epsilon^{2\theta} z = \{AD(D-1) + ED + g\}^{-1} \epsilon^{2\theta} M,$$

and is integrable if the two roots of the equation

$$Am(m-1) + Em + g = 0$$

differ by an odd integer. There are probably other cases dependent on the reduction of Art. (13).

In one respect Laplace's transformation possesses a generality superior to that of all others. For its tentative application fewer restrictions on the coefficients of the given equation are necessary. But, that the application may succeed, other conditions seem to be demanded which render the estimation of the true measure of its generality difficult. And, in particular instances, it is seen that it is less general than the method of the foregoing sections.

### *Miscellaneous Notices.*

15. Of special additions to the theory of the solution of differential equations by symbolical methods, the following may be noticed.

1st, Professor Donkin has shewn that, if  $f(x)$  be any function capable of development in powers of  $x$ , then whatever may be the interpretations of the symbols  $\pi$  and  $\rho$ , we have

$$f(\rho^{-1}\pi\rho)u = \rho^{-1}f(\pi)\rho u \dots\dots\dots (44).$$

This is evident from the consideration of such cases as the following:

$$\begin{aligned} (\rho^{-1}\pi\rho)^2 &= \rho^{-1}\pi\rho\rho^{-1}\pi\rho = \rho^{-1}\pi^2\rho, \\ (\rho^{-1}\pi\rho)^{-1} &= \rho^{-1}\pi^{-1}(\rho^{-1})^{-1} = \rho^{-1}\pi^{-1}\rho. \end{aligned}$$

We are thus enabled to generalize many important theorems.

Thus, since  $\left\{\frac{d}{dx} + \phi'(x)\right\}u = \epsilon^{-\phi(x)} \frac{d}{dx} \epsilon^{\phi(x)}u$ , we have

$$f\left\{\frac{d}{dx} + \phi'(x)\right\}u = \epsilon^{-\phi(x)} f\left(\frac{d}{dx}\right) \epsilon^{\phi(x)}u \dots\dots (45).$$

(*Cambridge Mathematical Journal*, 2nd Series, Vol. v. p. 10.)

2ndly, Mr Hargreave, observing that the symbols  $\frac{d}{dx}$  and  $-x$  are connected by the same laws as  $x$  and  $\frac{d}{dx}$  (the proof of this will afford an exercise for the student), has remarked that if in any differential equation and its *symbolic* solution we change  $x$  into  $\frac{d}{dx}$ , and  $\frac{d}{dx}$  into  $-x$ , we shall obtain another form accompanied by its symbolic solution. (*Philosophical Transactions* for 1848, Part I.)

Applying this law of duality to the known solution of the linear differential equation of the first order, it is easy to shew that the equation

$$x\phi(D)u + \psi(D)u = X$$

has for its symbolic solution,

$$u = \{\phi(D)\}^{-1} \epsilon^{x(D)} x^{-1} \epsilon^{-x(D)} X \dots \dots \dots (46),$$

where

$$\chi(D) = \int \frac{\psi(D)}{\phi(D)} dD,$$

a form which had before been established on other grounds (*Philosophical Magazine*, Feb. 1847). Many other illustrations of the same law will be found in the memoir of Mr Hargreave referred to.

3rdly, The method by which the development of  $f(\pi + \rho)$  is obtained in Art. 13, leads to other and similar results, of which the following is among the most interesting, viz.

$$f\left(x + \frac{d}{dx}\right) u = \{F(x) + F'(x) \frac{d}{dx} + \frac{1}{1.2} F''(x) \frac{d^2}{dx^2} + \&c.\} u \dots (47),$$

the coefficients of the expansion in the second member following the law of Taylor's theorem, and the function  $F(x)$  being equal to  $\epsilon^{\frac{1}{2}(\frac{d}{dx})^2} f(x)$ . (*Cambridge Mathematical Journal*, 1st Series, Vol. IV. p. 214.)

The last theorem enables us to integrate at once any equation of the form

$$F(x)u + F'(x) \frac{du}{dx} + \frac{1}{1.2} F''(x) \frac{d^2u}{dx^2} + \&c. = X,$$

where  $F(x)$  is a rational and integral function of  $x$ . For let

$$f(x) = e^{-\frac{1}{2} \frac{d^2}{dx^2}} F(x) = \left(1 - \frac{1}{2} \frac{d^2}{dx^2} + \frac{1}{1 \cdot 2} \frac{1}{4} \frac{d^4}{dx^4} - \&c.\right) F(x),$$

an expression always finite under the conditions supposed. Then the given equation assumes the form

$$f(\pi) u = X,$$

where  $\pi = x + \frac{d}{dx}$ , and may be treated by the method of the last section.

Other examples of the expansion of functions whose symbols are non-commutative—some of them admitting of a similar application—will be found in the memoir of Professor Donkin above referred to, and in an interesting memoir by Mr Brown (*Cambridge Mathematical Journal*, Vol. III. p. 36).

4thly, Many important partial differential equations of the second order admit of reduction to the form

$$\frac{du}{dx} \frac{dv}{dy} - \frac{du}{dy} \frac{dv}{dx} = 0,$$

whence an integral  $u = f(v)$  may be deduced. Thus the equation

$$\left(\frac{d\phi}{dp} \frac{d\psi}{dq} - \frac{d\phi}{dq} \frac{d\psi}{dp}\right) (rt - s^2) - \frac{d\phi}{dp} r - \left(\frac{d\phi}{dq} + \frac{d\psi}{dp}\right) s - \frac{d\psi}{dq} t + 1 = 0,$$

where  $\phi$  and  $\psi$  represent any given functions of  $p$  and  $q$ , may be expressed in the form

$$\frac{d(\phi - x)}{dx} \frac{d(\psi - y)}{dy} - \frac{d(\phi - x)}{dy} \frac{d(\psi - y)}{dx} = 0;$$

whence  $\phi - x = F(\psi - y)$  is a first integral. Mainardi has shewn that nearly all the equations which occur in Monge's *Application de l'Analyse à la Géométrie*, admit either of the above reduction, or of a purely symbolical mode of solution. (*Tortolini*, Vol. v. p. 161.)

5thly, The Author is indebted to Mr Spottiswoode of Oxford for an interesting communication on the laws of combination of symbols which are at the same time linear with respect

to  $\frac{d}{dx}$ ,  $\frac{d}{dy}$ , &c. and linear with respect to  $x$ ,  $y$ , &c. The following is one of the results. If, assuming

$$\pi_1 = x \frac{d}{dx} + y \frac{d}{dy}, \quad \pi_2 = y \frac{d}{dx} + x \frac{d}{dy},$$

a partial differential equation can be presented in the form

$$f(\pi_1, \pi_2) u = 0$$

on the assumption that  $\frac{d}{dx}$  and  $\frac{d}{dy}$  operate only on the subject  $u$ , then it can be expressed in the form  $F(\pi_1, \pi_2) u = 0$ , independently of such restrictive hypothesis. It might be added, that all such equations are reducible to equations with constant coefficients, by assuming

$$\log(x^2 + y^2)^{\frac{1}{2}} = x', \quad \log\left(\frac{x+y}{x-y}\right)^{\frac{1}{2}} = y'.$$

To the above might be added many other special deductions, isolated now, but destined perhaps, at some future time, to be embraced in the unity of a larger theory.

### EXERCISES.

1. Integrate  $x^2 \frac{d^2 u}{dx^2} + 4x \frac{du}{dx} - q^2 x^2 u = 0$ .
2. Integrate  $(x^2 - x^3) \frac{d^2 u}{dx^2} - (x + 3x^3) \frac{du}{dx} + (1 - x) u = 0$ .
3. Riccati's equation is reducible to the form

$$\frac{d^2 w}{dx^2} + bcx^m w = 0.$$

Hence investigate the conditions of integrability.

The symbolical form is  $w + \frac{bc}{D(D-1)} e^{(m+2)\theta} w = 0$ ; and this may either be reduced directly by Prop. III. to a form integrable by Prop. I, or, by assuming  $(m+2)\theta = 2\theta'$ , converted into a particular case of Art. 7 in the Chapter.

4. The equation  $\frac{d^2u}{dx^2} + \frac{a}{x} \frac{du}{dx} + bu = 0$  is integrable in finite terms if  $a$  is an even number.

5. The equation  $\frac{d^2u}{dx^2} + \frac{2r}{a} \frac{du}{dx} = bx^m u$  is integrable in finite terms if  $m = -\frac{4(i \pm r)}{2i \pm 1}$ , where  $i$  is a positive whole number or 0.

6. The more general equation

$$\frac{d^2u}{dx^2} + \frac{r}{a} \frac{du}{dx} = \left( bx^m + \frac{c}{x^2} \right) u,$$

which includes the above, is integrable in finite terms if

$$m + 2 = \frac{2\sqrt{\{(1-r)^2 + 4c\}}}{2i + 1},$$

$i$  being a positive whole number or 0. (Malmsten, *Cambridge Mathematical Journal*, 2nd Series, Vol. v. p. 180.) Verify this.

7. As an illustration of the theory of disappearing factors, integrate the equation

$$\begin{aligned} (x^2 + qx^3) \frac{d^2u}{dx^2} + \{(a+3)qx^2 + (b-i+1)x\} \frac{du}{dx} \\ + \{(a+1)qx - bi\} u = 0. \end{aligned}$$

8. The equation  $(1 - ax^2) \frac{d^2y}{dx^2} - bx \frac{dy}{dx} - cy = 0$  is integrable in finite terms in the following three cases; viz.

1st, If  $\frac{b}{a}$  is an odd integer;

2ndly, If  $\sqrt{\left\{\left(1 - \frac{b}{a}\right)^2 + \frac{4c}{a}\right\}}$  is an odd integer;

3rdly, If  $\frac{b}{a} + \sqrt{\left\{\left(1 - \frac{b}{a}\right)^2 + \frac{4c}{a}\right\}}$ , or  $\frac{b}{a} - \sqrt{\left\{\left(1 - \frac{b}{a}\right)^2 + \frac{4c}{a}\right\}}$ , is an even integer.

9. Integrate the partial differential equation

$$\frac{d^2 z}{dx^2} - \frac{d^2 z}{dy^2} - \frac{2}{x} \frac{dz}{dx} = 0.$$

10. The partial differential equation

$$\frac{d^2 z}{dx^2} - a^2 y^{2b} \frac{d^2 z}{dy^2} = 0$$

is integrable in finite terms if  $b = \frac{2i}{2i \pm 1}$ . (*Legendre*. See *Lacroix*, Tom. II. p. 618.) Verify this.

11. Shew that the sum of the series

$$1 \cdot 2 \dots nx + 2 \cdot 3 \dots (n+1)x^2 \dots + p(p+1) \dots (p+n-1)x^p$$

may be expressed in the form

$$x \left( \frac{d}{dx} \right)^n \frac{x^n - x^{p+n}}{1-x}.$$

12. Sum the series

$$1 + \frac{1^n x}{1} + \frac{2^n x^2}{1 \cdot 2} + \frac{3^n x^3}{1 \cdot 2 \cdot 3} + \&c.$$

13. The equation  $(a+bx) \frac{d^2 u}{dx^2} + (f+gx) \frac{du}{dx} + ngu = 0$  is integrable in finite terms if  $n$  is an integer.

Apply the method of Art. 13 to reduce the symbolical equation to a binomial form. Or assume  $a+bx=t$ .

14. The differential equation

$$\frac{d^2 u}{dx^2} + 2Q \frac{du}{dx} + \left\{ Q^2 + \frac{dQ}{dx} \pm c^2 - \frac{m(m+1)}{x^2} \right\} u = 0$$

can be integrated in finite terms, whatever function of  $x$  is represented by  $Q$ . (*Curtis*, *Cambridge Mathematical Journal*, Vol. ix. p. 280.)

The equation may be expressed in the form

$$\begin{aligned} & \left( \frac{d}{dx} + Q \right)^2 u \pm c^2 u - \frac{m(m+1)}{x^2} u = 0, \\ \text{or } & e^{-\int Q dx} \left( \frac{d}{dx} \right)^2 e^{\int Q dx} u \mp \left\{ c^2 \mp \frac{m(m+1)}{x^2} \right\} u = 0, \\ \text{or } & \left( \frac{d}{dx} \right)^2 e^{\int Q dx} u \pm \left\{ c^2 \pm \frac{m(m+1)}{x^2} \right\} e^{\int Q dx} u = 0. \end{aligned}$$

Let  $e^{\int Q dx} u = v$ ; then compare the resulting form with Ex. 8 of the Chapter.

15. Shew generally that, if we can integrate the equation

$$f \left( \frac{d}{dx} \right) u + \phi(x) u = X,$$

we can integrate  $f \left( \frac{d}{dx} + Q \right) u + \phi(x) u = X$ .

16. We meet the equation

$$\frac{d^2 y}{dc^2} + \frac{1-3c^2}{c-c^3} \frac{dy}{dc} - \frac{1}{1-c^2} y = 0,$$

in the theory of the elliptic functions (Legendre's modular equation). Shew that it is not integrable in finite terms, but is integrable in the form  $y = A + B \log c$ , where  $A$  and  $B$  are series expressed in ascending even powers of  $c$ .

17. Prove the following generalization of Prop. III.

$$F \{ \phi(D) \epsilon^{r\theta} \} = P_r \frac{\phi(D)}{\psi(D)} F \{ \psi(D) \epsilon^{r\theta} \} P_r \frac{\psi(D)}{\phi(D)}.$$

18. Prove the following still more general theorem,

$$F \{ D, \phi(D) \epsilon^{r\theta} \} = P_r \frac{\phi(D)}{\psi(D)} F \{ D, \psi(D) \epsilon^{r\theta} \} P_r \frac{\psi(D)}{\phi(D)}.$$

## CHAPTER XVIII.

### SOLUTION OF LINEAR DIFFERENTIAL EQUATIONS BY DEFINITE INTEGRALS.

1. THE solution of linear differential equations by definite integrals was first made a direct object of inquiry by Euler. His method consisted in assuming the form of the definite integral, and then, from its properties, determining the class of equations whose solution it is fitted to express. Laplace first devised a method of ascending from the differential equation to the definite integral. And Laplace's is still the most general method of procedure known. Its application is however not wholly free from difficulties, due partly to the present imperfection of the theory of definite integrals, partly to an occasional failure of correspondence in the conditions upon which continuity of form in the differential equation and continuity of form in its solution depend. Indeed it ought never to be employed without some means of testing the result *a posteriori*, e.g. by comparison with the solution of the proposed differential equation in series. Frequently indeed it is possible to deduce the solution in definite integrals from the solution in series without employing Laplace's method at all.

Laplace's method is applied with peculiar advantage to equations in the coefficients of which  $x$  enters only in the first degree, and of which the second member is 0. Expressing any such equation in the form

$$x\phi\left(\frac{d}{dx}\right)u + \psi\left(\frac{d}{dx}\right)u = 0 \dots\dots\dots (1),$$

we must assume

$$u = \int e^{x't} T dt,$$

$T$  being a function of  $t$ , the form of which, together with the limits of integration, must be determined by substituting the

expression for  $u$  in the proposed differential equation. Effecting this substitution, we have a result which may be thus expressed,

$$\int x \phi \left( \frac{d}{dx} \right) \epsilon^{xt} T dt + \int \psi \left( \frac{d}{dx} \right) \epsilon^{xt} T dt = 0,$$

or, since

$$\phi \left( \frac{d}{dx} \right) \epsilon^{xt} = \phi(t) \epsilon^{xt},$$

$$\int x \epsilon^{xt} \phi(t) T dt + \int \epsilon^{xt} \psi(t) T dt = 0 \dots \dots \dots (2).$$

Of this however, the first term is, by integration by parts, reducible to the form

$$\epsilon^{xt} \phi(t) T - \int \epsilon^{xt} \frac{d}{dt} \{ \phi(t) T \} dt.$$

Thus, (2) assumes the form

$$\epsilon^{xt} \phi(t) T - \int \epsilon^{xt} \left\{ \frac{d}{dt} [ \phi(t) T ] - \psi(t) T \right\} dt = 0 \dots \dots (3),$$

and will therefore be satisfied, if we make

$$\epsilon^{xt} \phi(t) T = 0,$$

$$\frac{d}{dt} \{ \phi(t) T \} - \psi(t) T = 0.$$

The former of these equations has reference only to the limits; the latter, expressed in the form

$$\frac{d}{dt} \{ \phi(t) T \} - \frac{\psi(t)}{\phi(t)} \{ \phi(t) T \} = 0,$$

gives on integration,

$$\phi(t) T = C \epsilon^{\int \frac{\psi(t)}{\phi(t)} dt},$$

and determines  $T$  in the form

$$T = \frac{C \epsilon^{\int \frac{\psi(t)}{\phi(t)} dt}}{\phi(t)}.$$

Thus, we have

$$u = C \int \frac{e^{xt + \int \frac{\psi(t)}{\phi(t)} dt}}{\phi(t)} dt \dots \dots \dots (4),$$

the limits of integration being determined by the equation

$$e^{xt + \int \frac{\psi(t)}{\phi(t)} dt} = 0 \dots \dots \dots (5).$$

Should this equation have  $n$  distinct roots, these may evidently be so disposed as to give  $n - 1$  distinct particular integrals.

Such is the general statement of Laplace's method. Applied to an equation in the coefficients of which the highest power of  $x$  involved is the  $n^{\text{th}}$ , it would make the determination of  $T$  depend on the solution of a differential equation of the  $n^{\text{th}}$  order. Other practical limitations may be noted. For instance, the method is only directly applicable to the expression of integrals which produce on development series of a certain form. Thus, if we develop the exponential in the assumed expression for  $u$ , we have

$$u = \int T dt + x \int T t dt + \frac{x^2}{1 \cdot 2} \int T t^2 dt + \&c.,$$

an expansion in which positive and integral powers of  $x$  alone present themselves. Integrals of different forms may, however, by preparation of the differential equation, be brought under the dominion of the method. These and other points we propose to illustrate by the detailed examination of a special but very important example, particular forms of which are of very frequent occurrence in physical inquiries. We shall first, in accordance with what has above been said, determine the different kinds of solution in series of which the equation admits. This part of the investigation is intended to be supplementary to Art. 9 of the last Chapter.

Ex. Given  $x \frac{d^2 u}{dx^2} + a \frac{du}{dx} - q^2 x u = 0.$

*Solutions expressed by Series.*

2. The symbolical form of the above equation is

$$u - \frac{q^2}{D(D+a-1)} \epsilon^{2\theta} u = 0 \dots \dots \dots (6).$$

Hence, if an integral be expressible in the form  $\sum u_m x^m$ , the law of formation of the coefficients  $u_m$  will be

$$u_m = \frac{q^2 u_{m-2}}{m(m+a-1)} \dots \dots \dots (7),$$

while the lowest value of  $m$  will be 0, or  $1-a$ . Thus, except in a particular case to be noticed hereafter, the complete integral will be

$$\begin{aligned} u = A \left\{ 1 + \frac{q^2 x^2}{2(a+1)} + \frac{q^4 x^4}{2.4(a+1)(a+3)} + \&c. \right\} \\ + Bx^{1-a} \left\{ 1 + \frac{q^2 x^2}{2.(3-a)} + \frac{q^4 x^4}{2.4(3-a)(5-a)} + \&c. \right\} \dots (8). \end{aligned}$$

The two series in the general value of  $u$  are evidently convergent for all values of  $x$ . As this question of the convergency of series is sometimes important in connexion with the solution of differential equations, the reader is reminded that according as, in the series of terms or groups of terms

$$u_0 + u_1 + u_2 + \&c.,$$

the ratio  $\frac{u_n}{u_{n-1}}$  tends, when  $n$  is indefinitely increased, to a limit less or greater than unity, the series is convergent or divergent; when the ratio is less than unity but tends to unity, we must apply a system of criteria developed by Professor De Morgan (*Differential and Integral Calculus*, p. 325\*).

\* That this system virtually includes previous special results has been proved by Bertrand (*Liouville*, Tom. vii. p. 35); that it is a legitimate development of the fundamental principles of Cauchy has been established by Paucker (*Crelle*, Band xlii. p. 138).

When  $a$  is an odd integer, the general integral will involve a logarithm. In particular if  $a=1$ , we shall have

$$u = a_0 + a_2x^2 + a_4x^4 + \&c. + \log x(b_0 + b_2x^2 + b_4x^4 + \&c.) \dots (9),$$

$a_0$  and  $b_0$  being arbitrary constants, and the succeeding coefficients determined by

$$m^2a_m + 2mb_m - q^2a_{m-2} = 0, \quad m^2b_m - q^2b_{m-2} = 0 \dots (10).$$

The symbolical equation (6) indicates by its form that there are no solutions expressible in descending powers of  $x$ , and infinite in one direction only—i.e. beginning with some finite exponent, and presenting a series of exponents thence descending. But the equation may be transformed so as to admit of a solution of this kind. For, assuming  $u = \epsilon^{-qx}v$ , we shall have

$$x \frac{d^2v}{dx^2} + (a - 2qx) \frac{dv}{dx} - aqv = 0,$$

and of this the symbolical form will be found to be

$$D(D + a - 1)v - 2q(D + \frac{a}{2} - 1)\epsilon^\theta v = 0 \dots (11);$$

whence, if  $v$  be developed in a series of the form  $\Sigma v_m x^m$ , the law of derivation of the coefficients will be

$$m(m + a - 1)v_m - 2q(m + \frac{a}{2} - 1)v_{m-1} = 0.$$

It follows from this that there will be two ascending and convergent series for  $v$ , and one descending and divergent series. The law of the latter series is, by changing  $m$  into  $m+1$ , more conveniently expressed in the form,

$$v_m = \frac{(m+1)(m+a)}{2q(m + \frac{a}{2})} v_{m+1}.$$

Hence, the first exponent will be  $-\frac{\alpha}{2}$ , and the ultimate value of  $u$  will be

$$u = C\epsilon^{-qx}x^{-\frac{\alpha}{2}}\left\{1 + \frac{\frac{\alpha}{2}\left(\frac{\alpha}{2}-1\right)}{1 \cdot 2qx} + \frac{\frac{\alpha}{2}\left(\frac{\alpha}{2}+1\right)\left(\frac{\alpha}{2}-1\right)\left(\frac{\alpha}{2}-2\right)}{1 \cdot 2 \cdot 4q^2x^2} + \&c.\right\} \quad (12).$$

If we assume  $u = \epsilon^{qx}v$ , and proceed as above, we shall obtain for  $v$  the symbolical equation,

$$D(D + \alpha - 1)v + 2q\left(D + \frac{\alpha}{2} - 1\right)\epsilon^q v = 0 \dots \dots \dots (13),$$

and as this differs from the previous equation for  $v$ , only by a change of sign affecting  $q$ , we at once deduce a second value of  $u$ , in the form

$$u = E\epsilon^{qx}x^{-\frac{\alpha}{2}}\left\{1 - \frac{\frac{\alpha}{2}\left(\frac{\alpha}{2}-1\right)}{1 \cdot 2qx} + \frac{\frac{\alpha}{2}\left(\frac{\alpha}{2}+1\right)\left(\frac{\alpha}{2}-1\right)\left(\frac{\alpha}{2}-2\right)}{1 \cdot 2 \cdot 4q^2x^2} - \&c.\right\} \quad (14),$$

the terms within the brackets being alternately positive and negative.

Both the descending series are finite when  $\alpha$  is an even integer, and though for all other values of  $\alpha$  they are infinite and ultimately divergent, yet if  $x$  be large they begin with being convergent, and may under certain circumstances be employed for numerical calculation.

Thus, we have obtained two solutions expressed in ascending series always convergent, and two solutions involving series expressed in descending powers of  $x$ , and ultimately divergent.

As concerns the convergent series for  $v$ , derivable from the transformed equations (11) and (13), we may remark that when multiplied by the developed exponentials, they will only reproduce the convergent series for  $u$  already obtained in (8).

One observation yet remains. We have seen that each of the assumptions  $u = \epsilon^{qx}v$  and  $u = \epsilon^{-qx}v$  transforms the proposed differential equation into another of which the solution in a

descending series is finite when the given equation admits of finite integration. This species of transformation is frequently possible. To accomplish it we must assume  $u = Qv$ , the form of  $Q$  being determined by the solution of that differential equation upon which, by Props. II. and III. Chap. XVII., the solution of the proposed equation, when possible in finite terms, is dependent.

*Solution of the Equation by Definite Integrals.*

3. Comparing the proposed equation,

$$x \frac{d^2 u}{dx^2} + a \frac{du}{dx} - q^2 xu = 0 \dots\dots\dots(15),$$

with the general form (1), we have

$$\phi \left( \frac{d}{dx} \right) = \frac{d^2}{dx^2} - q^2, \quad \psi \left( \frac{d}{dx} \right) = a \frac{d}{dx}.$$

Hence,

$$\phi(t) = t^2 - q^2, \quad \psi(t) = at;$$

therefore

$$\int \frac{\psi(t) dt}{\phi(t)} = \frac{a}{2} \log(t^2 - q^2).$$

Substituting these values in (4), we have

$$u = C \int \epsilon^{xt} (t^2 - q^2)^{\frac{a}{2}-1} dt \dots\dots\dots(16),$$

while, for the limits of integration, (5) gives

$$\epsilon^t (t^2 - q^2)^{\frac{a}{2}} = 0.$$

Hence, *supposing a positive*, and confining our attention for the present to the factor  $(t^2 - q^2)^{\frac{a}{2}}$ , which alone determines  $t$  in perfect independence of  $x$ , we find  $t = \pm q$ . Thus,

$$u = C \int_{-q}^q \epsilon^{xt} (t^2 - q^2)^{\frac{a}{2}-1} dt.$$

Assuming then  $t = q \cos \theta$ , and changing the sign of the arbitrary constant,

$$u = C_1 \int_0^\pi \epsilon^{qx \cos \theta} (\sin \theta)^{a-1} d\theta \dots\dots\dots (17),$$

and this, as its form suggests, and as we shall hereafter shew, is an expression for the particular integral represented by the first convergent series in the general value of  $u$ , given in (8).

To deduce another integral, let us in the symbolical equation (6) assume  $u = \epsilon^{(1-a)\theta} v$ . We find

$$v - \frac{q^2}{(D+1-a)D} \epsilon^{2\theta} v = 0 \dots\dots\dots (18).$$

Hence, a value of  $v$  may be determined from that of  $u$  by changing  $a-1$  into  $1-a$ ; i.e. by changing  $a$  into  $2-a$ . Thus we have, for the second particular integral,

$$u = C_2 x^{1-a} \int_0^\pi \epsilon^{qx \cos \theta} (\sin \theta)^{1-a} d\theta,$$

*provided that  $2-a$  be positive.*

Hence, if  $a$  lie between 0 and 2, we have for the complete integral,

$$u = C_1 \int_0^\pi \epsilon^{qx \cos \theta} (\sin \theta)^{a-1} d\theta + C_2 x^{1-a} \int_0^\pi \epsilon^{qx \cos \theta} (\sin \theta)^{1-a} d\theta \dots (19).$$

If  $a=1$ , the two particular integrals in the above expression merge into one. To deduce the true form of the general integral, we may proceed thus,

$$\begin{aligned} u &= \int_0^\pi \epsilon^{qx \cos \theta} \{ C_1 (\sin \theta)^{a-1} + C_2 (x \sin \theta)^{1-a} \} d\theta, \\ &= \int_0^\pi \epsilon^{qx \cos \theta} \left\{ A (\sin \theta)^{a-1} + B \frac{(\sin \theta)^{a-1} - (x \sin \theta)^{1-a}}{a-1} \right\} d\theta, \end{aligned}$$

on replacing  $C_1$  and  $C_2$  by two new arbitrary constants,  $A$  and  $B$ .

Now when  $\alpha = 1$ , we find by the usual mode of treating vanishing fractions,

$$\frac{(\sin \theta)^{\alpha-1} - (x \sin \theta)^{1-\alpha}}{\alpha - 1} = \log \{x (\sin \theta)^2\}.$$

Thus,

$$u = \int_0^\pi \epsilon^{qx \cos \theta} [A + B \log \{x (\sin \theta)^2\}] d\theta \dots\dots(20).$$

This is the complete integral of the equation

$$x \frac{d^2 u}{dx^2} + \frac{du}{dx} - q^2 x u = 0 \dots\dots\dots(21),$$

and a similar form exists for all cases in which  $\alpha$  is an odd integer.

4. We proceed to the cases in which  $\alpha$  is fractional and does not lie between the limits 0 and 2. By the application of Props. II. and III. Chap. XVII., this case can be reduced to the case in which  $\alpha$  does lie between the limits 0 and 2. First, suppose  $\alpha$  negative; then we may assume  $\alpha = \alpha' - 2n$ , where  $\alpha'$  lies between 0 and 2, and  $n$  is a positive integer. In this case, the first term of (19) will need transformation. Now the symbolical equation (6) becomes

$$u - \frac{q^2}{D(D + \alpha' - 2n - 1)} \epsilon^{2\theta} u = 0.$$

Hence, if we assume

$$v - \frac{q^2}{D(D + \alpha' - 1)} \epsilon^{2\theta} v = 0,$$

we shall have

$$\begin{aligned} u &= (D + \alpha' - 1)(D + \alpha' - 3) \dots (D + \alpha' - 2n + 1) v \\ &= \left(x \frac{d}{dx} + \alpha' - 1\right) \left(x \frac{d}{dx} + \alpha' - 3\right) \dots \left(x \frac{d}{dx} + \alpha' - 2n + 1\right) v \dots (22), \end{aligned}$$

in which

$$v = C_1 \int_0^\pi \epsilon^{qx \cos \theta} (\sin \theta)^{\alpha'-1} d\theta \dots\dots\dots(23).$$

And this particular expression for  $u$  must replace the first term in the general value of  $u$  given in (19). The differentiations may obviously be performed under the integral sign.

As a particular illustration suppose  $\alpha$  to lie between 0 and  $-2$ , then  $n=1$ ,  $\alpha = \alpha' - 2$ , whence

$$x \frac{d}{dx} + \alpha' - 1 = x \frac{d}{dx} + \alpha + 1.$$

The particular value of  $u$  which must replace the first term in the general value (19) will therefore be

$$u = C_1 \int_0^\pi \left( x \frac{d}{dx} + \alpha + 1 \right) \epsilon^{qx \cos \theta} (\sin \theta)^{\alpha+1} d\theta.$$

Effecting the differentiations, and substituting in (19), we have, for the general value of  $u$ ,

$$\begin{aligned} u = C_1 \int_0^\pi \epsilon^{qx \cos \theta} (qx \cos \theta + \alpha + 1) (\sin \theta)^{\alpha+1} d\theta \\ + C_2 x^{1-\alpha} \int_0^\pi \epsilon^{qx \cos \theta} (\sin \theta)^{1-\alpha} d\theta. \end{aligned}$$

Secondly, when  $\alpha$  is greater than 2, the assumption

$$u = \epsilon^{(1-\alpha)\theta} v, \quad \text{i.e. } u = x^{1-\alpha} v,$$

in effect converts  $\alpha$  into  $2 - \alpha$ . Compare (6) and (18). In effect, therefore, it converts  $\alpha$  into a negative quantity, and reduces the present case to the preceding one.

It remains only to notice that when  $\alpha$  is an even integer, the complete integral is expressible in finite terms. Chap. XVII. Art. 3.

Collecting these results together, we see that, according as  $\alpha$  is an even integer, a fraction, or an odd integer, the complete integral is expressible in finite terms, or by definite integrals producing on development two algebraic series, or by definite integrals producing on development two series, one of which is multiplied by the factor  $\log x$ . We propose before going farther to verify these results.

*Verification.*

5. If in the solution (19), we develop the exponentials, and for brevity write

$$\int_0^\pi (\cos \theta)^m (\sin \theta)^{a-1} d\theta = A_m, \quad \int_0^\pi (\cos \theta)^m (\sin \theta)^{1-a} d\theta = B_m \dots (24),$$

we shall have

$$u = C_1 \Sigma \frac{A_m}{1 \cdot 2 \dots m} q^m x^m + C_2 x^{1-a} \Sigma \frac{B_m}{1 \cdot 2 \dots m} q^m x^m \dots \dots (25),$$

the summation denoted by  $\Sigma$  extending to all positive integral values of  $m$ , from  $m=0$  to  $m=\infty$ . Thus the general value of  $u$  is expressed by two series, whose equivalence to the series given in (8) it remains to establish.

Now, when  $m$  is odd,  $A_m=0$ ,  $B_m=0$ , the positive and negative elements in each integral mutually destroying each other. Again, by a known formula of reduction,

$$\begin{aligned} \int (\cos \theta)^m (\sin \theta)^n d\theta &= \frac{(\cos \theta)^{m-1} (\sin \theta)^{n+1}}{m+n} \\ &+ \frac{m-1}{m+n} \int (\cos \theta)^{m-2} (\sin \theta)^n d\theta. \end{aligned}$$

Supposing the limits 0 and  $\pi$ , the term free from the sign of integration vanishes at each limit when  $n$  is positive, and we have, changing  $n$  successively into  $a-1$  and  $1-a$ ,

$$A_m = \frac{m-1}{m+a-1} A_{m-2}, \quad B_m = \frac{m-1}{m+1-a} B_{m-2} \dots \dots (26).$$

Now let the coefficient of  $x^m$  in the first series in (25) be represented by  $u_m$ , then

$$u_m = C_1 \frac{A_m q^m}{1 \cdot 2 \dots m}, \quad u_{m-2} = C_1 \frac{A_{m-2} q^{m-2}}{1 \cdot 2 \dots (m-2)};$$

therefore  $\frac{u_m}{u_{m-2}} = \frac{q^2 A_m}{m(m-1) A_{m-2}} = \frac{q^2}{m(m+a-1)}$  by (26).

Now this is the law of the coefficients assigned in (7). And just in the same way may the second series in (25) be verified. Thus the development of the general solution (19) produces the two convergent series of the solution in Art. 2.

The verification of the solution (20), though somewhat more difficult, may be effected on the same principles.

Developing the exponential, and assuming

$$\int_0^\pi (\cos \theta)^m d\theta = E_m, \quad \int_0^\pi (\cos \theta)^m (\log \sin \theta) d\theta = F_m,$$

we shall have

$$u = \Sigma \left( \frac{AE_m}{1.2\dots m} + \frac{2BF'_m}{1.2\dots m} \right) q^m x^m + \log x \Sigma \frac{BE_m}{1.2\dots m} q^m x^m \dots (27),$$

the summation extending to all even integral values of  $m$ , from  $m = 0$  to  $m = \infty$ .

Now it may be shewn that

$$E_m = \frac{m-1}{m} E_{m-2}, \quad F_m = \frac{m-1}{m} F_{m-2} - \frac{1}{m} E_m \dots \dots \dots (28),$$

and it will be found that these relations establish, for the coefficients of the series involved in (27), the same laws of successive derivation as are assigned in (10).

The verification of the solution (22) involves no difficulty.

### *Solution by Definite Integrals resumed.*

6. In Art. 3, we found for the equation of the limits,

$$\epsilon^{xt} (t^2 - q^2)^{\frac{a}{2}} = 0 \dots \dots \dots (29),$$

from which, in order to determine the limits in perfect independence of  $x$ , we rejected the factor  $\epsilon^{xt}$ . In the discussion of the same problem in the great work of Petzval\*, now in course of publication, that factor is retained, giving, according

\* *Integration der linearen Differentialgleichungen mit Constanten und veränderlichen Coefficienten.* [The second volume concluding the work was published in 1859.]

as  $x$  is positive or negative, the additional limit  $-\infty$  or  $\infty$ . And thus the following solutions are arrived at, viz.:

$$u = C_1 \int_{-q}^q \epsilon^{xt} (t^2 - q^2)^{\frac{\alpha}{2}-1} dt + C_2 \int_{-}^{-q} \epsilon^{xt} (t^2 - q^2)^{\frac{\alpha}{2}-1} dt \dots (30),$$

when  $x$  is positive, and

$$u = C_1 \int_{-q}^q \epsilon^{xt} (t^2 - q^2)^{\frac{\alpha}{2}-1} dt + C_2 \int_q^{\infty} \epsilon^{xt} (t^2 - q^2)^{\frac{\alpha}{2}-1} dt \dots (31),$$

when  $x$  is negative. It will be observed that it is in their second terms that the above expressions for  $u$  differ from the expression given in (19), and the question arises, what do those second terms really represent? We propose here to consider this question.

Supposing  $x$  positive, we have to examine the term

$$C_2 \int_{-\infty}^{-q} \epsilon^{xt} (t^2 - q^2)^{\frac{\alpha}{2}-1} dt.$$

Now this expression, on assuming  $t = -q(1 + \theta)$ , so as to make the limits of integration 0 and  $\infty$ , and performing reductions affecting only the arbitrary constant, becomes

$$C \int_0^{\infty} \epsilon^{-qx(1+\theta)} (2\theta + \theta^2)^{\frac{\alpha}{2}-1} d\theta,$$

or,  $C \epsilon^{-qx} \int_0^{\infty} \epsilon^{-qx\theta} (2\theta + \theta^2)^{\frac{\alpha}{2}-1} d\theta \dots (32).$

It is easy to see that this cannot produce either of the particular integrals represented by *ascending* developments in (8). For, if we develop the exponential under the sign of integration, the coefficient of  $x^m$  in the factor represented by the definite integral, will be

$$\frac{(-q)^m}{1 \cdot 2 \dots m} \int_0^{\infty} \theta^m (2\theta + \theta^2)^{\frac{\alpha}{2}-1} d\theta.$$

But,  $m$  and  $\alpha$  being positive, it is manifest that the expression is infinite.

We may, however, expand the definite integral in *descending* powers of  $x$ . Developing the binomial in ascending powers of  $\theta$ , and integrating by the well-known theorem

$$\int_0^\infty e^{-qx\theta} \theta^{\lambda-1} d\theta = \frac{\Gamma(\lambda)}{(qx)^\lambda},$$

(32) assumes the form

$$C e^{-qx} \left\{ \frac{2^{\frac{a}{2}-1} \Gamma\left(\frac{a}{2}\right)}{(qx)^{\frac{a}{2}}} + \frac{\left(\frac{a}{2}-1\right) 2^{\frac{a}{2}-1} \Gamma\left(\frac{a}{2}+1\right)}{(qx)^{\frac{a}{2}+1}} + \&c. \right\}.$$

Now observing that  $\Gamma\left(\frac{a}{2}+1\right) = \frac{a}{2} \Gamma\left(\frac{a}{2}\right) \&c.$ , substituting and merging the common factors in the arbitrary constant we have

$$C e^{-qx} x^{-\frac{a}{2}} \left\{ 1 + \frac{\left(\frac{a}{2}-1\right) \frac{a}{2}}{2qx} + \frac{\left(\frac{a}{2}-1\right) \left(\frac{a}{2}-2\right) \frac{a}{2} \left(\frac{a}{2}+1\right)}{1 \cdot 2 \cdot (2qx)^2} + \&c. \right\} \dots (33),$$

which agrees with (12). Exactly in the same way Petzval's second integral for the case in which  $x$  is negative, represents the other descending and divergent series (14).

7. We thus see the true nature of the distinction between Petzval's form of solution and those obtained in Art. 2. The latter represent the two converging and ascending series derived immediately from the differential equation. The former represents one of those series accompanied by the divergent series derived from a transformed differential equation\*.

\* Spitzer, in a recent Memoir in Crelle's *Journal* (Vol. LIV. p. 280), shews that when the coefficients of the differential equation

$$(a_2 + b_2 x) \frac{d^2 y}{dx^2} + (a_1 + b_1 x) \frac{dy}{dx} + (a_0 + b_0 x) y = 0$$

satisfy the condition  $a_1 b_2 - a_2 b_1 = b_2^2$ , the solution will be

$$y = \int e^{ux} V \left\{ A + B \log(a_2 + b_2 x) U_1 \right\} du$$

where

$$U_1 = b_2 u^2 + b_1 u + b_0, \quad \log(V U_1) = \int \frac{a_2 u^2 + a_1 u + a_0}{U_1} du,$$

It is known that in the employment of divergent series an important distinction exists between the cases in which the terms of the series are ultimately all positive, and alternately positive and negative. In the latter case we are, according to a known law, permitted to employ that portion of the series which is convergent for the calculation of its entire value. Now,  $a$  being positive, the series (12) assumes this character when  $x$  is positive, the series (14) when  $x$  is negative. But these are precisely the cases in which these series are represented by Petzval's integrals.

When, for the calculation of an element dependent on the solution of a differential equation, ascending and descending series are both employed (the former for small, the latter for large values of the independent variable), it is necessary to determine the connexion of the constants. For this purpose the expressions of the series by definite integrals may be of importance. On this, and on other points connected with this subject, the reader is referred to two most instructive Memoirs by Prof. Stokes\*, in which some of the equations of this chapter are applied to physical problems.

### *Partial Differential Equations.*

8. Some of the most interesting applications of the above method occur in the solution of partial differential equations. The following is an example.

Ex. Required the most general solution of the equation

$$\frac{d^2u}{dx^2} + \frac{d^2u}{dy^2} + \frac{d^2u}{dz^2} = 0,$$

and the limits are given by

$$e^{nx}U, V=0.$$

The deduction of this as a *limiting case of the general solution* may serve as an exercise to the student. It will be proper to assume  $a_2 + b_2x = v$  as the independent variable.

Spitzer expresses surprise that Petzval has not arrived at the above solution. We see however that it has no proper place in Petzval's actual scheme.

\* *On the Numerical Calculation of a Class of Definite Integrals and Infinite Series.* Cambridge Philosophical Transactions, Vol. ix. Part 1. p. 166.

*On the Effect of the Internal Friction of Fluids on the Motion of Pendulums.* Ibid. Part II. p. 8.

which can be expressed in terms of  $z$  and  $r$ , supposing

$$r = \sqrt{(x^2 + y^2)}.$$

This equation, with its supposed condition, presents itself in the problem of determining the attraction of a solid of revolution on an external point, and in the problem of the motion of an incompressible fluid, disturbed by the motion of a solid of revolution in the direction of the axis of revolution  $z$ .

The transformed equation is easily found to be

$$r \frac{d^2 u}{dr^2} + \frac{du}{dr} + r \frac{d^2 u}{dz^2} = 0 \dots\dots\dots (34).$$

Now the solution of the equation

$$r \frac{d^2 u}{dr^2} + \frac{du}{dr} + q^2 r u = 0,$$

is

$$u = \int_0^\pi \epsilon^{qr \cos \theta \sqrt{(-1)}} [A + B \log \{r (\sin \theta)^2\}] d\theta.$$

Hence, replacing  $q$  by  $\frac{d}{dz}$ , and  $A$  and  $B$  by arbitrary functions of  $z$ , we have, for the solution of (34),

$$u = \int_0^\pi \epsilon^{r \cos \theta \frac{d}{dz} \sqrt{(-1)}} [\phi(z) + \psi(z) \log \{r (\sin \theta)^2\}] d\theta,$$

or, by the symbolical form of Taylor's theorem,

$$\begin{aligned} u = & \int_0^\pi \phi \{z + r \cos \theta \sqrt{(-1)}\} d\theta \\ & + \int_0^\pi \psi \{z + r \cos \theta \sqrt{(-1)}\} \log \{r (\sin \theta)^2\} d\theta \dots\dots (35). \end{aligned}$$

Such is the complete integral.

In all physical problems involving partial differential equations the determination of the arbitrary functions so as to satisfy given initial conditions is a matter of great importance, and sometimes, where discontinuity presents itself, of great

difficulty. But though some general principles might be stated, the subject is best studied in the concrete application.

In applying the above solution to the problem of attraction it is required to determine the arbitrary functions so that when  $r = 0$  we should have  $u = F(z)$ . Now, since, when  $r = 0$ ,  $\log r$  is infinite, it is necessary to suppose  $\psi(z) = 0$ . We have then

$$F(z) = \int_0^\pi \phi(z) d\theta = \pi \phi(z).$$

Thus the solution under the proposed limitation becomes

$$u = \frac{1}{\pi} \int_0^\pi F\{z + r \cos \theta \sqrt{-1}\} d\theta.$$

### *Parseval's Theorem.*

9. Equations whose symbolical form is binomial generally admit of solution by definite integrals. Pfaff's equation has thus been treated by Euler. (Lacroix, Tom. III. p. 529.) The very beautiful theorem of Parseval, which makes the limit of the series  $AA' + BB' + CC' + \&c.$  dependent upon the limits of the series  $A + Bu + Cu^2 + \&c.$  and  $A' + \frac{B'}{u} + \frac{C'}{u^2} + \&c.$ , should be noticed.

Suppose that, for all values of  $u$ , real and imaginary,

$$A + Bu + Cu^2 \dots = \phi(u),$$

$$A' + \frac{B'}{u} + \frac{C'}{u^2} \dots = \psi(u).$$

Then, multiplying the equations together,

$$AA' + BB' + CC' + \dots + \Sigma \left( \alpha_m u^m + \frac{\beta_m}{u^m} \right) = \phi(u) \psi(u).$$

Assume, in succession,  $u = \epsilon^{\theta \sqrt{-1}}$  and  $u = \epsilon^{-\theta \sqrt{-1}}$ , and add the results.

We find

$$2(AA' + BB' + CC' + \dots) + 2\Sigma (\alpha_m \cos m\theta) + 2\Sigma (\beta_m \cos m\theta) \\ = \phi \{ \epsilon^{\theta\sqrt{(-1)}} \} \psi \{ \epsilon^{\theta\sqrt{(-1)}} \} + \phi \{ \epsilon^{-\theta\sqrt{(-1)}} \} \psi \{ \epsilon^{-\theta\sqrt{(-1)}} \}.$$

Now multiply by  $d\theta$ , integrate between the limits 0 and  $\pi$ , observing that  $\int_0^\pi (\cos m\theta) d\theta = 0$ , and divide the result by  $2\pi$ , then

$$AA' + BB' + \dots = \frac{1}{2\pi} \int_0^\pi [\phi \{ \epsilon^{\theta\sqrt{(-1)}} \} \psi \{ \epsilon^{\theta\sqrt{(-1)}} \} \\ + \phi \{ \epsilon^{-\theta\sqrt{(-1)}} \} \psi \{ \epsilon^{-\theta\sqrt{(-1)}} \}] d\theta \dots\dots (36),$$

which is the theorem in question.

### *Solution of Differential Equations by Fourier's Theorem.*

10. As Fourier's theorem affords the only general method known for the solution of partial differential equations with more than two independent variables (and such are the equations upon which many of the most important problems of mathematical physics depend), we deem it proper to explain at least the principle of this application, referring the reader for a fuller account of it to two memoirs by Cauchy\*.

As a particular example, let us consider the equation

$$\frac{d^2u}{dt^2} - h^2 \left( \frac{d^2u}{dx^2} + \frac{d^2u}{dy^2} + \frac{d^2u}{dz^2} \right) = 0 \dots\dots\dots (37).$$

Let  $u = \phi(x, y, z, t)$  represent any solution of this equation. By a well-known form of Fourier's theorem,

$$\phi(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} da d\lambda \epsilon^{(a-x)\lambda\sqrt{(-1)}} \phi(a),$$

\* *Sur l'Intégration d'Equations Linéaires. Exercices d'Analyse et de Physique Mathématique, Tom. I. p. 53.*

*Sur la Transformation et la Réduction des Intégrales Générales d'un Système d'Equations Linéaires aux différences partielles. Ibid. p. 178.*

successive applications of which enable us to give to  $u$  the form

$$u = \frac{1}{8\pi^3} \iiint_{-\infty}^{\infty} \iiint_{-\infty}^{\infty} \epsilon^{A\sqrt{(-1)}} \phi(a, b, c, t) da db dc d\lambda d\mu d\nu \dots (38),$$

where  $A = (a - x)\lambda + (b - y)\mu + (c - z)\nu$ .

Substituting this expression in (37), and observing that from the form given to  $A$  we have

$$\left( \frac{d^2}{dx^2} + \frac{d^2}{dy^2} + \frac{d^2}{dz^2} \right) \epsilon^{A\sqrt{(-1)}} = \epsilon^{A\sqrt{(-1)}} (-\lambda^2 - \mu^2 - \nu^2),$$

we have

$$\frac{1}{8\pi^3} \iiint_{-\infty}^{\infty} \iiint_{-\infty}^{\infty} \epsilon^{A\sqrt{(-1)}} \left\{ \frac{d^2}{dt^2} + h^2 (\lambda^2 + \mu^2 + \nu^2) \right\} \phi da db dc d\lambda d\mu d\nu = 0,$$

$\phi$  being put for  $\phi(a, b, c, t)$ . This equation will be satisfied if  $\phi$  be determined so as to satisfy the equation

$$\frac{d^2 \phi}{dt^2} + h^2 (\lambda^2 + \mu^2 + \nu^2) \phi = 0.$$

Hence, integrating and introducing arbitrary functions of  $a, b, c$  in the place of arbitrary constants, we have the particular integrals,

$$\phi = \epsilon^{Bht\sqrt{(-1)}} \psi_1(a, b, c), \quad \phi = \epsilon^{-Bht\sqrt{(-1)}} \chi_1(a, b, c) \dots (39),$$

where  $B = (\lambda^2 + \mu^2 + \nu^2)^{\frac{1}{2}}$ .

Substituting the first of these values in (38), and merging the factor  $\frac{1}{8\pi^3}$  in the arbitrary function, we have

$$u = \iiint_{-\infty}^{\infty} \iiint_{-\infty}^{\infty} \epsilon^{(A+Bht)\sqrt{(-1)}} \psi_1(a, b, c) da db dc d\lambda d\mu d\nu \dots (40),$$

a particular integral of the proposed equation. It may easily be shewn that the employment of the second value of  $\phi$  given in (39) would only lead to an equivalent result.

To complete the solution, we observe that if, representing  $\frac{d^2}{dx^2} + \frac{d^2}{dy^2} + \frac{d^2}{dz^2}$  by  $H$ , we make  $t = \epsilon^\theta$ , so as to reduce the given equation to the symbolical form,

$$u - \frac{H}{D(D-1)} \epsilon^{2\theta} u = 0,$$

then, by Propositions II. and III. Chap. XVII., the transformation  $u = \epsilon^{-\theta} \frac{dv}{d\theta} = \frac{dv}{dt}$ , will give

$$v - \frac{H}{D(D-1)} \epsilon^{2\theta} v = 0,$$

which is of the same form as the equation for  $u$ . Hence,  $v$  admitting of expression in the form (40), we have, on merely changing the arbitrary function,

$$u = \frac{d}{dt} \iiint_{-\infty}^{\infty} \epsilon^{(A+Bht)} \sqrt{(-1)} \psi_2(a, b, c) da db dc d\lambda d\mu dv \dots (41).$$

The complete integral is thus expressed by the sum of the particular integrals (40) and (41). The sextuple integral by which the above particular values of  $u$  are expressed admits of reduction to a double integral leading to a form of solution originally obtained by Poisson. Cauchy effects this reduction by a trigonometrical transformation. It may be accomplished, and perhaps better, by other means; but this is a matter of detail which does not concern the principle of the solution. We may add, that when the function to be integrated becomes infinite within the limits, Cauchy's method of residues should be employed. The reduced integral in its trigonometrical form, together with Poisson's method of solution, which is entirely special, will be found in Gregory's Examples, p. 504.

Cauchy's method is directly applicable to equations with second members, and to systems of equations. The above example belongs to the general form

$$\frac{d^2 u}{dt^2} = Hu,$$

where  $H$  is a function of  $\frac{d}{dx}$ ,  $\frac{d}{dy}$ ,  $\frac{d}{dz}$ . For all such equations the method furnishes directly a solution expressed by sextuple integrals, which are reducible to double integrals if  $H$  is homogeneous and of the second degree. In the above example the double integration proves to be, in effect, an integration extended over the surface of a sphere whose radius increases uniformly with the time. Integrals of this class are peculiarly appropriate for the expression of those physical effects which are propagated through an elastic medium, and leave no trace behind.

### MISCELLANEOUS EXERCISES.

1. The complete integral of the equation

$$\frac{d^2u}{dx^2} = \left\{ h^2 + \frac{n(n+1)}{x^2} \right\} u,$$

is expressible in the form  $u = A\epsilon^{hx} + B\epsilon^{-hx}$ ,  $A$  and  $B$  being series which are finite when  $n$  is an integer. (Tortolini, Vol. v. p. 161.)

2. The definite integral  $\int_0^\pi \cos \{n(\theta - x \sin \theta)\} d\theta$ , can be evaluated when  $n = \pm \left(i + \frac{1}{2}\right)$ , where  $i$  is a positive integer or 0. (Liouville, *Journal*, Tom. VI. p. 36.)

Representing the definite integral by  $u$ , it will be found that  $u$  satisfies an equation of the form  $\frac{d^2u}{dx^2} = \left(A + \frac{B}{x^2}\right) u$ .

The subject of the evaluation of definite integrals by the solution of differential equations has been treated with great generality by Mr Russell (*Philosophical Transactions* for 1855).

3. If  $v = \alpha$  be the equation of a system of curves,  $v$  being a function of  $x$  and  $y$  which satisfies the equation  $\frac{d^2v}{dx^2} + \frac{d^2v}{dy^2} = 0$ , and if  $u = \beta$  be the equation of the orthogonal trajectories of the system, then  $u$  may be found by the integration of an

exact differential equation of the first order, and when found will satisfy the equation  $\frac{d^2u}{dx^2} + \frac{d^2u}{dy^2} = 0$ .

The above theorem is applied by Professor Thomson to the problem of determining the forms of the rings and brushes in the spectra produced by biaxial crystals. (*Cambridge Journal*, 2nd Series, Vol. I. p. 124.)

4. The normal at a point  $P$  of a plane curve meets the axis in  $G$ , and the locus of the middle point of  $PG$  is the parabola  $y^2 = lx$ . Find the equation to the curve, supposing it to pass through the origin. (*Cambridge Problems*.)

5. The normal at any point of a surface passes through the line represented by  $\frac{x}{l} = \frac{y}{m} = \frac{z}{n}$ . Find the differential equation to the surface, and obtain the general integral. (*Ib.*)

6. Prove that the differential equation of the surfaces generated by a straight line which passes through the axis of  $z$ , and through a given curve, and which makes a constant angle with the axis of  $z$ , is

$$x \frac{dz}{dx} + y \frac{dz}{dy} = \sqrt{(x^2 + y^2)} \cot \alpha. \quad (Ib.)$$

7. Integrate the above equation.

8. Express by a definite integral the series,

$$1 - \frac{x^2}{2^2} + \frac{x^4}{2^2 \cdot 4^2} - \frac{x^6}{2^2 \cdot 4^2 \cdot 6^2} + \&c.$$

Form the differential equation by Chap. xvii. Art. 11, and then apply Laplace's method, Chap. xviii. The result is  $u = \frac{2}{\pi} \int_0^{\frac{\pi}{2}} \cos(x \cos \theta) d\theta$ . (Stokes, *Cambridge Transactions*, Vol. ix. p. 182.)

9. Hence express the series in a form suitable for calculation when  $x$  is large.

Proceeding according to the directions of Chap. xviii. the complete integral of the differential equation expressed by descending series will be

$$u = x^{-\frac{1}{2}} \{ (A \cos x + B \sin x) R + (A \sin x - B \cos x) S \},$$

where

$$R = 1 - \frac{1^2 \cdot 3^2}{1 \cdot 2 (8x)^2} + \frac{1^2 \cdot 3^2 \cdot 5^2 \cdot 7^2}{1 \cdot 2 \cdot 3 \cdot 4 (8x)^4} - \&c.$$

$$S = \frac{1^2}{1 \cdot 8x} - \frac{1^2 \cdot 3^2 \cdot 5^2}{1 \cdot 2 \cdot 3 (8x)^3} + \&c.$$

The values of  $A$  and  $B$  for the particular integral in question will be  $A = B = \pi^{-\frac{1}{2}}$ . These are deduced from the consideration that, when  $x$  tends to infinity, we have, in the limit,

$$\frac{2}{\pi} \int_0^{\frac{\pi}{2}} \cos(x \cos \theta) d\theta = (\pi x)^{-\frac{1}{2}} (\cos x + \sin x). \quad (Ibid.)$$

The above series occurs in several physical problems.

10. The complete integral of the equation,

$$x \frac{d^2 y}{dx^2} + (a + bx) \frac{dy}{dx} + (f + gx + hx^2) y = 0,$$

may be expressed by a finite formula involving general differentiation. (Attributed to Liouville.)

Assume  $y = ze^{\alpha x + \frac{\beta x^2}{2}}$ ; then, by a proper determination of  $\alpha$  and  $\beta$ , the equation may be reduced to the form

$$x \frac{d^2 z}{dx^2} + (\alpha' + b'x) \frac{dz}{dx} + f'z = 0.$$

The symbolical equation obtained by assuming  $x = e^\theta$  will be binomial, and the integration in the required form may be effected by Prop. III. Chap. XVII.

11. Equations of the form

$$x^2 \frac{d^2 y}{dx^2} + (A_1 + B_1 x^m) x \frac{dy}{dx} + (A_0 + B_0 x^m + C_0 x^{2m}) y = 0,$$

may be reduced to the form,

$$t\phi\left(\frac{d}{dt}\right)z + \psi\left(\frac{d}{dt}\right)z = 0 \dots\dots\dots(m),$$

considered in Chap. XVIII.

Assume  $x^m = t$ ,  $y = t^k z$ ; the determination of  $k$  will be found to depend on the equation  $k(k-1)m^2 + k\{m(m-1) + mA_1\} + A_0 = 0$ .

Petzval, *Linearen Differentialgleichungen*, Pt. Ist, p. 105. Riccati's equation is included in the above.

12. Equations of the form

$$(a_0 + b_0 \log x) x^2 \frac{d^2 u}{dx^2} + (a_1 + b_1 \log x) x \frac{du}{dx} + (a_2 + b_2 \log x) u = 0$$

are reducible to the form  $(m)$ . (*Ib.* p. 112.)

13. The complete integral of the equation

$$\frac{d^n y}{dx^n} = (\alpha + \beta x) y,$$

is 
$$y = \int_0^\infty dt e^{-\frac{t^{n+1}}{n+1}} (C e^{tx} + C_1 \rho e^{\rho t x} \dots + C_n \rho^n e^{\rho^n t x}),$$

where  $\rho$  is a primitive root of  $\rho^{n+1} = 1$ , and  $C, C_1, C_2 \dots C_n$ , satisfy the condition  $C + C_1 + C_2 \dots + C_n = 0$ , but are otherwise arbitrary. (Jacobi, *Crelle's Journal*, Vol. x. p. 279.)

14. The determination of the orthogonal trajectory of any system of straight lines on a plane, involving in their general equation one variable parameter, can be effected by the solution of an exact differential equation between  $x$  and  $y$ .

This interesting proposition, together with the following demonstration, was communicated to the author by Professor Donkin, with whose permission it is published.

The equation of the given system can always be expressed in the form  $x \sin \theta - y \cos \theta = \phi(\theta)$ , or, putting  $\cos \theta = u$ ,  $\sin \theta = v$ ,

$$vx - uy - F(u, v) = 0 \dots \dots \dots (1),$$

$$u^2 + v^2 - 1 = 0 \dots \dots \dots (2).$$

The equation of the trajectory will then be

$$u dx + v dy = 0 \dots \dots \dots (3),$$

$u$  and  $v$  being determined from (1) and (2) as functions of  $x$  and  $y$ .

Now, if we represent the first members of (1) and (2) by  $F$  and  $\Phi$  respectively, then, in order that (3) may be an exact differential equation, we must have, in virtue of (37) Chap. XIV.

$$\frac{dF}{dx} \frac{d\Phi}{du} - \frac{dF}{du} \frac{d\Phi}{dx} + \frac{dF}{dy} \frac{d\Phi}{dv} - \frac{dF}{dv} \frac{d\Phi}{dy} = 0 \dots \dots \dots (4),$$

and this will be found to be identically satisfied. Hence (3) is an exact differential equation, as was to be shewn. The proposition applies generally to the problem of involutes. Thus, the tangents to a circle being represented by

$$vx - uy = a, \quad u^2 + v^2 = 1,$$

the equation (3) will become

$$\frac{\{x \sqrt{(x^2 + y^2 - a^2)} - ay\} dx + \{y \sqrt{(x^2 + y^2 - a^2)} + ax\} dy}{x^2 + y^2} = 0.$$

This is exact, and determines, on integration, the system of possible involutes.

15. To determine the connexion of the integrals of any system of simultaneous differential equations expressible in the form

$$\left. \begin{aligned} \frac{dx}{dt} &= \frac{dF}{du}, & \frac{dy}{dt} &= \frac{dF}{dv} \\ \frac{du}{dt} &= -\frac{dF}{dx}, & \frac{dv}{dt} &= -\frac{dF}{dy} \end{aligned} \right\} \dots\dots\dots (1),$$

where  $F$  is a given function of  $x, y, u$  and  $v$ .

The complete solution will evidently consist of four equations determining  $x, y, u, v$  as functions of  $t$ , and four arbitrary constants.

Suppose that there exists an integral of the form  $\Phi = c$ , where  $\Phi$  is a function of  $x, y, u, v$ , not involving  $t$ . Then, differentiating, we have

$$\frac{d\Phi}{dx} \frac{dx}{dt} + \frac{d\Phi}{dy} \frac{dy}{dt} + \frac{d\Phi}{du} \frac{du}{dt} + \frac{d\Phi}{dv} \frac{dv}{dt} = 0,$$

or substituting for  $\frac{dx}{dt}, \frac{dy}{dt}, \&c.$  the values given in (1),

$$\frac{d\Phi}{dx} \frac{dF}{du} + \frac{d\Phi}{dy} \frac{dF}{dv} - \frac{d\Phi}{du} \frac{dF}{dx} - \frac{d\Phi}{dv} \frac{dF}{dy} = 0 \dots\dots\dots (2).$$

Now this equation is identically satisfied if  $\Phi = F$ . Hence one integral will be  $F = a$ , where  $a$  is an arbitrary constant.

Suppose now that another integral not involving  $t$  can be found. Then representing it by  $\Phi = b$ , and observing that (2) is identical with the equation (4) in the last problem, it is seen that if, from the two equations  $F = a, \Phi = b$ , we determine  $u$  and  $v$  as functions of  $x, y, a, b$ , the expression  $u dx + v dy$  will be an exact differential. Hence, if  $\int (u dx + v dy) = \chi$ , we have

$$u = \frac{d\chi}{dx}, \quad v = \frac{d\chi}{dy} \dots\dots\dots (3).$$

Now differentiating the integral  $F = a$  with respect to  $a$ , and regarding  $u, v$ , as functions of  $x, y, a, b$ , we have

$$\frac{dF}{du} \frac{du}{da} + \frac{dF}{dv} \frac{dv}{da} = 1,$$

or, putting for  $\frac{dF}{du}, \frac{dF}{dv}$  their values given in (1), and for  $u, v$  their values given in (3),

$$\frac{d^2\chi}{da dx} \frac{dx}{dt} + \frac{d^2\chi}{da dy} \frac{dy}{dt} = 1,$$

or

$$\frac{d}{dx} \left( \frac{d\chi}{da} \right) dx + \frac{d}{dy} \left( \frac{d\chi}{da} \right) dy = dt,$$

whence, integrating,

$$\frac{d\chi}{da} = t + c \dots\dots\dots (4),$$

$c$  being an arbitrary constant. Since the form of  $\chi$  is known, this constitutes a third integral.

Lastly, differentiating  $F=a$  with respect to  $b$  and proceeding as above, we find

$$\frac{d\chi}{db} = e \dots\dots\dots (5),$$

$e$  being an arbitrary constant. And this is the fourth integral.

The above is a simple illustration of the methods of Theoretical Dynamics referred to in Chap. XIV. Thus the equations for the motion of a body attracted towards fixed centres (all in one plane) are

$$\frac{d^2x}{dt^2} = -\frac{dR}{dx}, \quad \frac{d^2y}{dt^2} = -\frac{dR}{dy},$$

$R$  being a function of  $x, y$ , and the co-ordinates of the fixed centres. These equations may be expressed in the form

$$\begin{aligned} \frac{dx}{dt} &= u, \quad \frac{dy}{dt} = v, \\ \frac{du}{dt} &= -\frac{dR}{dx}, \quad \frac{dv}{dt} = -\frac{dR}{dy}. \end{aligned}$$

Now, if we represent the function  $\frac{1}{2}(u^2 + v^2) + R$  by  $F$ , the above equations assume the general form (1).

It was intimated in Chap. XIV. that the solution of the equations of Dynamics is finally dependent on the obtaining of the complete primitive of a non-linear partial differential equation of the first order; and this was previously shewn to depend on the integration of an *exact* differential equation the coefficients of which were determined by the solution of a *linear* partial differential equation of the first order. Now all this agrees with what has been exemplified above. For the last two integrals, (4) and (5) are derived, by mere differentiation, from  $\chi$ , while  $\chi$  is found by the integration of an *exact* differential equation whose coefficients,  $u$  and  $v$ , are obtained from equations which satisfy the *linear* partial differential equation (2).

The student is especially referred to the original memoirs by Sir W. R. Hamilton (*On a General Method in Dynamics. Philosophical Transactions, 1834—5*), to various memoirs by Jacobi contained in his collected works or scattered through Crelle's *Journal*, and to the recent memoirs of Prof. Donkin (*On a Class of Differential Equations including those of Dynamics. Philosophical Transactions, 1854—5*). Liouville's *Journal* is rich in valuable memoirs on the subject.

## ANSWERS.

The following table does not contain answers to all the questions proposed in the Exercises, but to a selected number of them, thought amply sufficient for ordinary requirements.

### CHAPTER I.

2. (1)  $y = px + \sqrt{1 + p^2}$ . (Here,  $p = \frac{dy}{dx}$ ).  
 (2)  $p - ay = e^{ax}$ . (3)  $(1 + x^2)p + y = \tan^{-1}x$ .  
 (4)  $xp + y = y^2 \log x$ . (5)  $yp^2 + 2xp = y$ .  
 (6)  $y = xp + \phi(p)$ .
3. (1) and (2)  $\frac{d^2y}{dx^2} + m^2y = 0$ . (3)  $x^3 \frac{d^2y}{dx^2} + \left(y - x \frac{dy}{dx}\right)^2 = 0$ .
6. (1)  $(x - a)^2 + (y - b)^2 = 1$ . (2)  $bx - ay = ab(xy - 1)$ .
8.  $x - \frac{m}{p^2} = a$ ,  $y - \frac{2m}{p} = b$ ,  $x - \frac{m}{p^2} = f\left(y - \frac{2m}{p}\right)$ .
9.  $(y - c)^2 = 4c'x$ .

### CHAPTER II.

1. (1)  $\log xy + x - y = c$ . (2)  $\log \frac{x}{y} - \frac{y + x}{xy} = c$ .  
 (3)  $(1 + x^2)(1 + y^2) = cx^2$ .  
 (4)  $\frac{x}{\sqrt{1 + x^2}} - \frac{1}{2} \log(1 + y^2) - \log\{y + \sqrt{1 + y^2}\} = c$ .  
 (5)  $\cos y = c \cos x$ . (6)  $\tan x \tan y = c$ .
2. Yes. 3. (1)  $y = c\epsilon^{-\frac{x}{y}}$ . (2)  $y = c\epsilon^{-\sqrt{\frac{x}{y}}}$ .
- (3)  $x^2 = c^2 + 2cy$ . (4)  $x = c\epsilon^{-\sin \frac{y}{x}}$ . (5)  $(y + x)^2(y + 2x)^3 = c$ .
4. (1)  $x^2 - xy + y^2 + x - y = c$ . (2)  $(y - x + 1)^2(y + x - 1)^5 = c$ .

$$5. \quad y = Cx^a + \frac{x}{1-a} - \frac{1}{a}.$$

$$6. \quad (2) \quad y = ax + cx\sqrt{1-x^2}. \quad (3) \quad y = c\epsilon^{-\frac{x}{\sqrt{1-x^2}}} + \frac{x}{\sqrt{1-x^2}}.$$

$$(4) \quad y = \sin x - 1 + c\epsilon^{-\sin x}. \quad (5) \quad y = \tan^{-1}x - 1 + c\epsilon^{-\tan^{-1}x}.$$

$$10. \quad (1) \quad z = \{c\sqrt{1-x^2} - a\}^{-1}. \quad (2) \quad z^3 = c\epsilon^{ax} - \frac{x+1}{a} - \frac{1}{a^2}.$$

$$(3) \quad z = \{c\epsilon^{2x^2} + \frac{a}{2}(2x^2+1)\}^{-\frac{1}{2}}. \quad (5) \quad y = (cx + \log x + 1)^{-1}.$$

## CHAPTER III.

$$1. \quad x^4 + 6x^2y^2 + y^4 = C. \quad 2. \quad x^2 - y^2 = cx. \quad 3. \quad x^2 - y^2 = cy^3.$$

$$4. \quad \frac{x^2 + y^2}{2} + \tan^{-1} \frac{y}{x} = c. \quad 5. \quad x + y\epsilon^{\frac{x}{y}} = c.$$

$$6. \quad \epsilon^x (x^2 + y^2) = c. \quad 7. \quad \sin (nx + my) + \cos (mx + ny) = c.$$

$$9. \quad \sqrt{1+x^2+y^2} + \tan^{-1} \frac{x}{y} = c, \quad \sin^{-1} \sqrt{x^2+y^2} + \sin^{-1} \frac{x}{y} + \epsilon^{\frac{x}{y}} = c.$$

$$10. \quad \text{Assuming } \frac{y}{x^a} = v, \text{ we have } \int \frac{dv}{c - bv^2} = \frac{x^a}{a} + C.$$

## CHAPTER IV.

$$2. \quad \frac{1}{y^3 - x^2y}. \quad 3. \quad \frac{1}{y^4} f\left(\frac{x^2 - y^2}{y^3}\right).$$

$$4. \quad xy f(x^2 + xy - y^2).$$

Complete primitive is  $x^2 + xy - y^2 = c$ .

$$5. \quad (1) \quad \text{Integrating factor, } \frac{1}{x\sqrt{x^2+y^2}}. \quad \text{Solution, } x^2 = c^2 + 2cy.$$

$$(2) \quad \text{Integrating factor, } \frac{1}{2x^2 + 3xy + y^2}.$$

$$\text{Solution, } (y+x)^2 (y+2x)^3 = c.$$

$$(4) \quad y = c \sqrt{1 + \frac{2y}{x}}. \quad (5) \quad xy \cos \frac{y}{x} = c.$$

$$6. \quad y = cx \text{ is the complete primitive.}$$

$$7. \quad (1) \quad \frac{1}{xy(xy+1)}. \quad (2) \quad \frac{1}{x^3y^3 + x^2y^2}.$$

## CHAPTER V.

1. (1)  $\epsilon^x$ . (2)  $\frac{1}{x^2}$ . 2.  $y^{-4}$ . (3)  $\epsilon^{\frac{x}{y}}$ , and  $\frac{1}{y^2}$ .

4. (2)  $y^{-3}\epsilon^{-\frac{ax}{y}}$ . (3)  $y^{-1}\epsilon^{\frac{x}{y}}$ . (4)  $(1+y^2-x^2)^{-2}$ .  
 (5)  $(x^3+y)^{-2}$ . (6)  $(x+y+xy)^{-2}$ . (7)  $(x+y^2)^{-3}$ .

5.  $\epsilon^x (x^2+y^2)^{-\frac{3}{2}} = c$ .

7. If  $z + P = y$  the equation becomes  $\frac{dz}{dx} + 2Pz = -z^2$ , which is of the general form of 6.

9. When  $\frac{n-1}{n^2} Q = \frac{d}{dx} \cdot \frac{P}{Q}$ . Then  $f(x) = -\frac{nP}{Q}$ .

## CHAPTER VI.

Equations 1 to 5 must be reduced to the form

$x \frac{dy}{dx} - \alpha y + by^2 = cx^{2a}$ , of which the solution is

$$y = x^a \sqrt{\left(\frac{c}{b}\right) \frac{C\epsilon^{\frac{2\sqrt{(bc)x^a}}{a}} + 1}{C\epsilon^{\frac{2\sqrt{(bc)x^a}}{a}} - 1}}, \text{ or } y = x^a \sqrt{\left(-\frac{c}{b}\right) \tan\left\{C - \frac{\sqrt{(-bc)x^a}}{a}\right\}},$$

according as  $b$  and  $c$  are like or unlike in sign. In 1 we find  $i=1$ , and the solution by (A) is  $y = a + \frac{x^{-2a}}{y_1}$ , where  $y_1$  is given by changing, in the first of the above solutions,  $a$  into  $-a$ ,  $b$  into 1,  $c$  into 1. In 2,  $i=2$ ; apply (A). In 3 apply (D).

7.  $\sqrt{(\beta^2 - 4\alpha\gamma)} + n(i + \frac{1}{2}) = 0$ ,  $i$  being any integer, positive, negative, or 0.

9.  $x \frac{dy}{dx} - (2A^2 + 1)y + by^2 = cx^{m+2}$ , where  $A$  is a root of the equation  $bA^2 + A - h = 0$ .

10. Compare with p. 95.

## CHAPTER VII.

1.  $(y - 2x - c)(y - 3x - c) = 0$ .
2.  $(y - a \log x - c)(y + a \log x - c) = 0$ .
5. Eliminate  $p$  by means of  $a \log p + 2bp + c = x$ .
6. By  $y = \frac{ap^3}{2} + \frac{2bp^3}{3} + c$ .
8. By  $y = \frac{ap^3}{2} + \frac{p}{2} \sqrt{1 + p^2} - \frac{1}{2} \log \{p + \sqrt{1 + p^2}\} + c$ .
12. Complete Primitive  $y = cx + c - c^2$ .  
Singular Solution  $y = \frac{(x + 1)^2}{4}$ .
13. Complete Primitive,  $y = cx + \sqrt{b^2 - a^2 c^2}$ .  
Singular Solution,  $-\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ .      14.  $x^2 + y^2 = cx$ .
16. Eliminate  $p$  by  $x = \frac{p}{\sqrt{1 - p^2}} (c + a \sin^{-1} p)$ .
17. By  $x = \frac{p}{\sqrt{1 + p^2}} (c + \frac{a}{p} + a \tan^{-1} p)$ .
19.  $(x - a)^2 + \{y - f(a)\}^2 = 1$ .      21.  $ax - yf(a) = af(a)(xy - 1)$ .

## CHAPTER VIII.

4. Singular Solution  $x = a$ .
6. Differential equation,  $p = \frac{1}{2\sqrt{x - a}}$ .
10. (1)  $xy = 1$ .      (2)  $\left(\frac{x}{m}\right)^{\frac{1}{2}} \pm \left(\frac{y}{n}\right)^{\frac{1}{2}} = 1$ .      (3)  $y = \frac{(x - 1)^2}{4}$ .
11. Particular Integral.
13. Singular solution  $y = 0$ ; complete primitive  $y = e^{a(x^2 - 1)}$ .

16. (1) Envelope species,  $y = \frac{-x^4}{4}$ .  
 (2) Envelope species,  $y^2 = 4x^2$ .  
 (3) Not of envelope species,  $y = x^n$ .
17. Singular solution,  $\sqrt{x} + \sqrt{y} = a$ .
18. Singular solution,  $x^{\frac{2}{3}} + y^{\frac{2}{3}} = a^{\frac{2}{3}}$ .
19.  $x = \cos^{-1} y^{\frac{1}{2}} + (y - y^2)^{\frac{1}{2}}$ .

## CHAPTER IX.

1.  $y = c\epsilon^{3x} + c'\epsilon^{4x}$ .      2.  $y = c\epsilon^{3x} + c'\epsilon^{4x} + \frac{12x+7}{144}$ .
3.  $y = \epsilon^x (c_0 + c_1x + c_2x^2 + c_3x^3)$ .
4.  $y = (c_1 + c_2x) \cos x + (c_3 + c_4x) \sin x$ .
5.  $y = c\epsilon^{-x} + (c_1 + c_2x) \epsilon^{2x}$ .
6.  $y = c_1 \cos x + c_2 \sin x + (c_3 + c_4x) \epsilon^x + 1$ .
7.  $y = (c_1 + c_2x) \epsilon^{kx} + \frac{\epsilon^x}{(k-1)^2}$ .      8.  $y = \left(c_1 + c_2x + \frac{x^2}{2}\right) \epsilon^x$ .
9.  $y = cx^3 + \frac{c'}{x}$ .      10.  $y = c(x+a)^2 + c'(x+a)^3$ .
11.  $y = \epsilon^{\frac{b, r^2}{2}} \{c \cos (x\sqrt{b}) + c' \sin (x\sqrt{b})\}$ .
12.  $y = c\epsilon^{a \sin^{-1} x} + c_1\epsilon^{-a \sin^{-1} x}$ .
14. Add  $x^2$  to the previous value of  $y$ .

## CHAPTER X.

$$1. \quad y = \frac{x^3}{6} - \sin x + c + c'x. \quad 3. \quad x = \frac{a^{\frac{1}{4}}}{2} \int \frac{dy}{\sqrt{(c + \sqrt{y})}} + c'.$$

$$4. \quad y = c \log x + c'. \quad 5. \quad y = cx^2 + \frac{c'}{x}.$$

$$7. \quad x + c = (y^2 - a^2)^{\frac{1}{2}}. \quad 8. \quad y = \frac{cx^2}{2} + f(c)x + c'.$$

$$9. \quad x = \frac{1}{c} \log \{cy + f(c)\} + c'.$$

$$14. \quad y = \epsilon^{-\int P dx} \left( \int \epsilon^{\int P dx} C dx + C' \right). \quad 19. \quad y = cx.$$

$$20. \quad y = -a + \frac{1}{2} (a\epsilon^{\frac{x}{a}} + a\epsilon^{-\frac{x}{a}}). \quad 22. \quad x + c + (c_1^{\frac{2}{3}} - y^{\frac{2}{3}})^{\frac{3}{2}} = 0.$$

$$23. \quad y = c \log \{x + c + \sqrt{(x^2 + 2cx)}\} + c'.$$

$$26. \quad t = \int \frac{dx}{\left( C\epsilon^{-\frac{k}{x^2}} + \frac{\mu}{k} \right)^{\frac{1}{2}}} + C'.$$

$$28. \quad x^2 \frac{d^2y}{dx^2} - x \frac{dy}{dx} + xy^2 = c. \quad 31. \quad \left( \frac{dy}{dx} \right)^2 - x^2 = 0.$$

$$32. \quad (y - c)^2 - \frac{x^4}{4} = 0. \quad 33. \quad y = \frac{1}{2a} \left( \frac{x^3}{3} + a^2x + b \right).$$

## CHAPTER XI.

$$1. \quad x = cy^n. \quad 2. \quad x + c = \frac{1}{n} \log \{ny + \sqrt{(n^2y^2 - 1)}\}.$$

$$4. \quad 2cx + c' = b \left( \frac{c^2 y^{\frac{b-a}{b}}}{b-a} - \frac{y^{\frac{b+a}{b}}}{b+a} \right).$$

6. Let  $y^2 = 2cx - x^2$  represent the circles, then the trajectory is  $x^2 = 2c'y - y^2$ .

$$7. \quad y^2 + x^2 - c = 2a^2 \log x. \quad 8. \quad \text{An equiangular spiral.}$$

$$10. \quad 4ay + c = 2ax \sqrt{(4a^2x^2 - 1)} - \log \{2ax + \sqrt{(4a^2x^2 - 1)}\}.$$

## CHAPTER XII.

1.  $(x-a)(y-b)(z-c) = C.$
2.  $x^2 + 2y^2 - 6xy - 2xz + z^2 = C.$
3.  $yz + zx + xy = c.$
5.  $e^x(y+z) = c.$
6.  $\frac{a}{x} + \frac{b}{y} + \frac{c}{z} = C.$
7.  $\frac{y+z}{x} + \frac{z+x}{y} = C.$
8.  $e^{x^2}(x+y+z^2) = C.$
9.  $x^2 + xy^2 - w + x^2z = c.$
10. No.

## CHAPTER XIII.

1.  $x = ce^{-\frac{7t}{2}} - \frac{y}{2}, \quad y = (ct + c_1)e^{-\frac{7t}{2}}.$
2.  $y = e^{-6t}(c \cos t + c' \sin t),$   
 $x = \frac{e^{-6t}}{2} \{(c + c') \sin t + (c - c') \cos t\}.$
5.  $x + y = ce^{-4t} + \frac{e'}{5} + \frac{e^{2t}}{6}, \quad x - 2y = c'e^{-7t} + \frac{e'}{8} - \frac{2e^2}{9}.$
7.  $x = \frac{1}{7} + 4c_1e^{2t} + 4c_2e^{-2t} - c_3e^{t\sqrt{7}} - c_4e^{-t\sqrt{7}},$   
 $y = \frac{9}{14} + c_1e^{2t} + c_2e^{-2t} - c_3e^{t\sqrt{7}} - c_4e^{-t\sqrt{7}}.$

## CHAPTER XIV.

$$2. \quad z = y \sin^{-1} \frac{x}{y} + \phi(y). \quad 3. \quad \epsilon^{-\frac{z}{y}}(x + y + z) = \phi(y).$$

$$5. \quad z = \frac{x}{a} + \phi(ay - bx). \quad 6. \quad z = \epsilon^{\frac{y}{a}} \phi(x - y).$$

$$7. \quad z = (x + y) \phi(x^2 - y^2). \quad 8. \quad z = \frac{y^2}{3x} + \phi(xy).$$

$$9. \quad \frac{y-b}{z-c} = \phi\left(\frac{x-a}{z-c}\right). \quad 10. \quad z^2 = xy + \phi\left(\frac{x}{y}\right).$$

$$11. \quad x^2 + y^2 + z^2 = z \phi\left(\frac{y}{z}\right).$$

$$13. \quad x + \sqrt{(x^2 + y^2 + z^2)} = x^{1-a} \phi\left(\frac{y}{x}\right). \quad 15. \quad z = c \sqrt{(x^2 + y^2)}.$$

$$16. \quad (a-1)z + \frac{xy}{t} = x^a \phi\left(\frac{y}{x}, \frac{t}{x}\right).$$

$$18. \quad \text{Complete Primitive } z = ax + by + ab. \quad 19. \quad z = -xy.$$

$$20. \quad z = ax + \frac{y}{a} + b. \quad 21. \quad z = ax\epsilon^y + \frac{a^2}{2} \epsilon^{2y} + b.$$

$$23. \quad z = xy + y \sqrt{(x^2 - a^2)} + b \text{ and } z = \frac{x-y}{a} + \frac{ay}{x-y} + b.$$

## CHAPTER XV.

$$2. \quad z = x \phi\left(\frac{y}{x}\right) + \psi\left(\frac{y}{x}\right). \quad 3. \quad y = x \phi(z) + \psi(z).$$

$$4. \quad x = f(y) + \phi(z). \quad 5. \quad x = F(z) + f(x + y + z).$$

$$8. \quad z = \phi(x + ay) + y \sqrt{(-1 - a^2)}.$$

## CHAPTER XVI.

1.  $u = c + \left(c_1 + c_2 x + \frac{x^2}{2}\right) \epsilon^x.$
2.  $\frac{\epsilon^{mx}}{m^2 - 5m + 6} + c\epsilon^{2x} + c'\epsilon^{3x}.$
3.  $u = c\epsilon^{2x} + c'\epsilon^{3x} - x\epsilon^{2x}.$
4.  $u = \epsilon^{3x} \left(\frac{x^2}{2} + \frac{3}{2}x + \frac{7}{4}\right) + c\epsilon^{4x} + c'\epsilon^{5x}.$
5.  $u = \frac{3m \sin mx - (m^2 - 2) \cos mx}{9m^2 + (m^2 - 2)^2} + c_1 \epsilon^{-x} + c_2 \epsilon^{-2x}.$
8.  $u = x^n \phi\left(\frac{y}{x}\right) + x \psi\left(\frac{y}{x}\right).$
9.  $u = \frac{(x^2 + y^2)^{\frac{n}{2}}}{n(n-1)} + x \phi\left(\frac{y}{x}\right) + \psi\left(\frac{y}{x}\right).$
10.  $u = \cos(n \log x) \phi\left(\frac{y}{x}, \frac{z}{x}\right) + \sin(n \log x) \psi\left(\frac{y}{x}, \frac{z}{x}\right).$
11. Assume  $\frac{d}{dx} + X = \pi.$

## CHAPTER XVII.

1.  $u = c\epsilon^x (x-1) - c'\epsilon^x (x+1).$
2.  $u = \left(x^2 \frac{d^2}{dx^2} + x \frac{d}{dx}\right) \frac{c + c' \log x}{1-x}.$
7.  $u = x^a \left(\frac{d}{dx}\right)^a c_1 - \frac{c_2 \int x^{b-1} (1+qx)^{a-b} dx}{x^b (1+qx)^{a-b+1}}.$
9.  $z = \left(x \frac{d}{dx} - 1\right) \{\phi(y+x) + \psi(y-x)\}.$
12.  $\left(x \frac{d}{dx}\right)^n \epsilon^x.$

*Note on Art. 4 of Chap XIV, page 327.*

[The language here used is not quite satisfactory. It is asserted that from equation (7) we *must* have the two equations (8) since  $\phi'(v)$  is arbitrary. But by the same argument it would follow on page 326 that we *must* have

$$\frac{du}{dx} + \frac{du}{dz} p = 0, \quad \text{and} \quad \frac{dv}{dx} + \frac{dv}{dz} p = 0,$$

also 
$$\frac{du}{dy} + \frac{du}{dz} q = 0, \quad \text{and} \quad \frac{dv}{dy} + \frac{dv}{dz} q = 0.$$

In fact, instead of saying that the two equations (8) *must* hold, we ought to say that we may consistently with (7) *assume* them both to hold. Then it will follow that the relations (9) must be consistent with the relation  $pdx + qdy = dz$ . This is sufficient to enable us to deduce the equation (10).

Traces of the same inaccuracy of language will be found in other parts of the Treatise, though not so decided as in the present passage : see pages 333 and 363.

This correction is due to the Rev. H. W. Watson, formerly Fellow of Trinity College.]

## CHAPTER XIX.

### ADDITIONS TO CHAPTER II.

1. [IN Chapter II. Art. 9, two methods are given for solving the differential equation

$$(ax + by + c) dx + (a'x + b'y + c') dy = 0.]$$

But there exists another transformation by which the equation may be reduced to, (because it may be constructed from), an equation in which the variables are separated.

Assume as this equation

$$(Ay' + C) dx' + (A'x' + C') dy' = 0 \dots (1)$$

and let  $x' = x + m_1y, \quad y' = x + m_2y.$

It will be seen that in these equations united we have as many constants as in the original equation. Now on substituting in the assumed equation the values of  $x'$  and  $y'$ , and comparing with the equation given, we deduce a system of relations equivalent to the following, viz.:

The quantities  $m_1, m_2$  are roots of the quadratic

$$am^2 - (b + a')m + b' = 0.$$

The quantities  $A, A', C, C'$  are determined by the system of equations

$$\begin{aligned} A + A' &= a, & C + C' &= c, \\ Am_1 + A'm_2 &= a', & Cm_1 + C'm_2 &= c', \end{aligned}$$

from which we find

$$A = \frac{am_2 - a'}{m_2 - m_1}, \quad C = \frac{cm_2 - c'}{m_2 - m_1},$$

$$A' = \frac{am_1 - a'}{m_1 - m_2}, \quad C' = \frac{cm_1 - c'}{m_1 - m_2}.$$

Now (1) gives on dividing by  $(A'x' + C')$   $(Ay' + C)$  and integrating

$$\frac{1}{A'} \log (A'x' + C') + \frac{1}{A} \log (Ay' + C) = \text{const.},$$

or 
$$(A'x' + C')^{\frac{1}{A'}} (Ay' + C)^{\frac{1}{A}} = \text{const.},$$

which on substitution and reduction gives

$$\frac{\{(am_1 - a')(x + m_1y) + cm_1 - c'\}^{\frac{1}{am_1 - a'}}}{\{(am_2 - a')(x + m_2y) + cm_2 - c'\}^{\frac{1}{am_2 - a'}}} = \text{const.} \dots (2)$$

2. Under certain circumstances the general solutions of differential equations of the first order fail. This happens in the above example if  $m_2 = m_1$ , the solution then reducing to

$$1 = \text{const.}$$

The theory of the deduction of the true limiting form of the solution in such cases requires a distinct statement.

Let the supposed general solution be represented by

$$u = C,$$

$C$  being the arbitrary constant and  $u$  a function of  $x, y$ , and constants which are not arbitrary. Suppose too that when one of these constants  $k$  assumes a particular value  $\kappa$ , the function  $u$  reduces to a constant  $v$ . Then we have

$$\frac{u - v}{k - \kappa} = \frac{C - v}{k - \kappa}.$$

Now the second member being a function of an arbitrary constant is equivalent to an arbitrary constant and may be

replaced by  $C$ . The first member is a vanishing fraction, the limiting value of which is  $\left(\frac{du}{dk}\right)$ , the brackets being used to denote that after the differentiation  $k$  is to be made equal to  $\kappa$ . Hence the solution becomes

$$\left(\frac{du}{dk}\right) = C.$$

In applying this theory to the reduction of the general solution (2) in the case in which  $m_1 = m_2$ , it must be observed that the numerator of the first member is the same function of  $m_1$ ,  $x$ ,  $y$ , as the denominator is of  $m_2$ ,  $x$ ,  $y$ ; or attending solely to their functional character with respect to  $m_1$ ,  $m_2$ , we may affirm that the numerator is the same function of  $m_1$  as the denominator is of  $m_2$ . Representing these functions by  $\phi(m_1)$ ,  $\phi(m_2)$  respectively, we have

$$u = \frac{\phi(m_1)}{\phi(m_2)}.$$

But  $m_1$ ,  $m_2$  being roots of a quadratic equation may be represented in the form

$$m_1 = m + k, \quad m_2 = m - k,$$

the roots becoming equal when  $k = 0$ . Hence

$$u = \frac{\phi(m + k)}{\phi(m - k)}.$$

Therefore since

$$\frac{d\phi(m + k)}{dk} = \frac{d\phi(m + k)}{dm}, \quad \frac{d\phi(m - k)}{dk} = -\frac{d\phi(m - k)}{dm},$$

we have

$$\frac{du}{dk} = \frac{\phi(m - k) \frac{d\phi(m + k)}{dk} - \phi(m + k) \frac{d\phi(m - k)}{dk}}{\{\phi(m - k)\}^2};$$

therefore

$$\left(\frac{du}{dk}\right) = \frac{2\phi(m) \frac{d\phi(m)}{dm}}{\{\phi(m)\}^2} = \frac{2 \frac{d\phi(m)}{dm}}{\phi(m)} = 2 \frac{d}{dm} \log \phi(m).$$

Thus the solution becomes on putting  $C$  for  $\frac{C}{2}$ ,

$$\frac{d}{dm} \log \phi(m) = C,$$

or

$$\frac{d}{dm} \frac{1}{am - a'} \log \{(am - a')(x + my) + cm - c'\} = C.$$

3. [The next Article seems to have been intended to appear in the enlarged form of Chap. II.; but I cannot discover what precise position it would have occupied. I conjecture that “the above demonstration” refers to Chap. II. Arts. 2, 3; and I have accordingly supplied a reference to equation (3) of Chap. II.

I had myself drawn Professor Boole’s attention to Chap. II. Arts. 2, 3. The geometrical process of Chap. II. Art. 3, appears to have been first given by D’Alembert in his *Opuscules*, Vol. IV. p. 255. D’Alembert calls it a *demonstration*; it seems to me only an *illustration*, at least in the brief form of the text: and that such was Cauchy’s opinion may perhaps be inferred from the elaborate investigation given by Moigno, to which Professor Boole refers in Art. 5 of the present Chapter.

I had also drawn Professor Boole’s attention to the statement at the end of Chap. II. Art. 12, that only *one* arbitrary constant was involved. Accordingly Article 5 of the present Chapter develops this statement, and Article 4 seems intended to bear on the same subject.]

4. In the above demonstration the relation between  $y$  and  $x$  is regarded as one of pure magnitude, and the interpretation of the differential equation becomes a limiting case of that of the equation of *finite* differences (Eq. (3), Chap. II.). But if we represent  $x$  and  $y$  by the rectangular co-ordinates

of a moving point on a plane the differential equation may be interpreted directly. For supposing it reduced to the form

$$\frac{dy}{dx} = f(x, y),$$

we see that the direction of motion is constantly assigned as a function of the co-ordinates of position. The entire motion is therefore determinate as soon as the initial point is fixed. The result of the motion is a line or curve wholly continuous or subject to irregularities according to the nature of the function  $f(x, y)$ . That the arbitrariness of origin is geometrically equivalent to the appearance of a single arbitrary constant in the relation connecting  $x$  and  $y$  may be shewn thus.

Let  $y = \phi(x_0, y_0, x)$

be the relation between  $x$  and  $y$  indicated by the supposed motion,  $x_0, y_0$  being the initial point of departure. Then this point being on the line of motion,  $x_0, y_0$  are particular values of  $x$  and  $y$ , so that we have from the above equation

$$y_0 = \phi(x_0, y_0, x_0),$$

which establishes a relation between  $x_0$  and  $y_0$ , and shews that there exists virtually but one arbitrary constant.

5. It is proved in Art. 3, Chap. II., that the constants  $x_0, y_0$ , initial values of the variables  $x, y$  in the solution of the differential equation of the first order, are necessarily equivalent to one *arbitrary* constant. I shall shew from the form of the above solution that this *a priori* condition is actually satisfied.

Developing the expression for  $y$  [see Eq. (30) of Chap. II.] in ascending powers of  $x$ , we have

$$y = A_0 + A_1x + \frac{A_2x^2}{1 \cdot 2} + \frac{A_3x^3}{1 \cdot 2 \cdot 3} + \&c., \dots\dots (32)$$

in which  $A_r = \sum \frac{f_n(x_0, y_0) (-x_0)^{n-r}}{1 \cdot 2 \dots (n-r)},$

the summation extending from  $n=r$  to  $n=\infty$ . Forming

hence the differential coefficients of  $A_r$  with respect to  $x_0$  and  $y_0$ , and reducing by (28), we shall find

$$\frac{dA_r}{dx_0} + f_1(x_0, y_0) \frac{dA_r}{dy_0} = 0,$$

whence in particular

$$\frac{dA_0}{dx_0} + f_1(x_0, y_0) \frac{dA_0}{dy_0} = 0.$$

Eliminate between these equations  $f_1(x_0, y_0)$ , and we have

$$\frac{dA_r}{dx_0} \frac{dA_0}{dy_0} - \frac{dA_r}{dy_0} \frac{dA_0}{dx_0} = 0.$$

Therefore, by Prop. I.,  $A_r$  is a function of  $A_0$ , so that the solution reduced to the form (32) contains but the single arbitrary constant  $A_0$ .

It remains to notice that the solution must be applied only under the conditions of convergency, i.e. under the condition that the ratio of the  $n^{\text{th}}$  to the  $(n-1)^{\text{th}}$  term tends to a limit less than unity as  $n$  tends to infinity. For a discussion of the failing cases of this test see 'Finite Differences,' Chap. v. Generally it is desirable, in order to secure rapid convergency, to divide the interval  $x - x_0$  into separate equal portions, to each of which the general theorem of solution may be applied. If  $x - x_0$  be very small the theorem may be approximately represented by

$$y - y_0 = f(x_0, y_0) (x - x_0).$$

On these principles Cauchy has founded remarkable methods of solution, which deserve attention from the commentary on the limits of error on their application by which they are accompanied (Moigno, Vol. II. pp. 385—434).

## CHAPTER XX.

### ADDITIONS TO CHAPTER VII.

1. [THIS Article relates to Art. 2 of Chap. VII.]

The sense in which (9) may be said to constitute the general solution of the differential equation is this. We obtain from it

$$y = C\epsilon^{ax}, \quad y = C\epsilon^{-ax};$$

giving any particular value to  $C$  this will geometrically represent a curve consisting of two branches, and giving to  $C$  every possible value we obtain an infinite system of such curves, each consisting of two branches. The aggregate of branches thus obtained is evidently the same as the aggregate of curves given by the two primitives (5) and (6), unrestricted by any connexion between  $c_1$  and  $c_2$ . In this sense then the solution (9) is general, that it includes all the particular relations between  $y$  and  $x$  which are deducible from the original primitives (5) and (6). And it is only in this sense not general that it groups these relations together in a particular manner.

To the expression of the complete primitive a certain variety of form may be given without affecting its generality in the sense above affirmed. Thus, if to the solutions of the component differential equations we give the forms

$$y\epsilon^{-ax} - c_1 = 0, \quad \log y + ax - c_2 = 0,$$

we should have, by the same procedure, as the expression of the complete primitive,

$$(y\epsilon^{-ax} - c)(\log y + ax - c) = 0,$$

an equation which may equally with (9) be regarded as the complete primitive of the differential equation given, and which in geometry represents the same totality of branches of curves as (9), with this difference only, that they are differently paired together.

2. [This Article relates to Art. 3 of Chap. VII.]

The question will here naturally arise, Since if  $V=c$  be a solution of one of the component differential equations,  $f(V)=c$ , in which  $f(V)$  denotes any function of  $V$ , is also a solution, by Chap. IV. Art. 3, why not give to the complete primitive the form

$$\{f_1(V_1) - c\} \{f_2(V_2) - c\} \dots \dots \dots \{f_n(V_n) - c\} = 0,$$

or the stricter form

$$f_1(V_1) f_2(V_2) \dots \dots \dots f_n(V_n) = 0 \dots \dots \dots (F),$$

in which  $f_1(V_1)$ ,  $f_2(V_2)$ , ...  $f_n(V_n)$  denote arbitrary functions of  $V_1$ ,  $V_2$ , ...,  $V_n$  respectively—stricter because the presence of arbitrary constants and functions in the previous form is a superfluous generality? It is replied that though the form just given is analytically more general than (15), it is not more general than (15) with such freedom as is permitted in the interpretation of the arbitrary constants. In a physical or geometrical application we should not only be permitted to assign a particular value to the arbitrary constant in (15), so deducing what in reference to its source would then be termed a particular primitive, but to combine the results of different determinations of  $c$  together, so as to obtain every form of solution which is implied either in the functional equation  $(F)$ , or in its component primitives

$$V_1 = c_1, \quad V_2 = c_2 \dots, \quad V_n = c_n.$$

The same considerations justify us in speaking of (15) as the complete primitive, and not as a complete primitive.

## CHAPTER XXI.

### ADDITIONS TO CHAPTER VIII.

1. [THE Singular Solutions of Differential Equations of the First Order received great attention from Professor Boole, and the Chapter devoted to that subject is one of the most valuable and important in his work. He continued his researches after the publication of his first edition, and intended to reconstruct the Chapter with great improvements in the second edition. After carefully examining the manuscripts I came to the conclusion that it would be very difficult to rewrite this portion of the work so as to connect the old matter with the new ; and thus it seemed best to reprint the original Chapter VIII. with corrections of obvious misprints, and to print the matter intended for the revised form in the present volume. The plan gives rise to some repetition ; but this seems unimportant, compared with the advantage of preserving in the author's own language all that he left on an interesting and important point which he had carefully studied.

2. It may be of service to the student to reproduce the substance of some remarks on his Chapter VIII. which were sent to Professor Boole soon after the publication of his first edition ; for there is evidence in his manuscripts that he paid great attention to such remarks while engaged in the revision of his work, and thus the reason and the meaning of some of his additions and changes may be made more obvious. These remarks will occupy the next Article.

3. The two pages beginning with “ And these conditions are sufficient,” and ending with “ do not lead to *conflicting*

*results,*" forming part of Arts. 3 and 4 of Chapter VIII., seem obscure and difficult. The following may perhaps be substituted with advantage.

The only ways in which

$$\frac{dy}{dx} = \frac{df(x, c)}{dx} \quad \text{and} \quad \frac{dy}{dx} = \frac{df(x, c)}{dx} + \frac{df(x, c)}{dc} \frac{dc}{dx}$$

can be equivalent when  $c$  is variable, are

- (1) when  $\frac{df(x, c)}{dc} = 0$ ,
- (2) when  $\frac{df(x, c)}{dx} = \infty$ ;

in the latter case  $\frac{dy}{dx} = \infty$ , and therefore  $\frac{dx}{dy} = 0$ , and this implies that the singular solution is of the form  $x = \text{constant}$ . Thus there can be no singular solutions except such as are found from  $\frac{df(x, c)}{dc} = 0$ , and such as are found from  $x = \text{constant}$ .

Similarly, if the complete primitive be expressed in the form  $x = F(y, c)$ , there can be no singular solutions except such as are found from  $\frac{dF(y, c)}{dc} = 0$ , and such as are found from  $y = \text{constant}$ .

In Art. 8 of Chapter VIII. we read, "We may pass over the case in which the above equation is satisfied independently of  $c$ , because the relation obtained would involve  $x$  only, while it is a condition accompanying the use of  $\frac{dp}{dy} = \infty$  that it leads to solutions involving  $y$  at least." It is objected, Why may we pass over this case? Such a case might occur and furnish a solution, and then we should want to know the character of that solution. Take for example  $p = x^n y$ ; here if  $n$  is negative,  $\frac{dp}{dy}$  is infinite when  $x = 0$ , and this is a singular solution. For the general solution is  $y = c e^{\frac{x^{n+1}}{n+1}}$ ,

and so  $x=0$  is not a case of it. The words—*while it is a condition...at least*—seem very difficult, for by supposition we are now investigating what is furnished by  $\frac{dp}{dy} = \infty$ .

Professor Boole met the objection in substance thus :

“It will be found that the rules in the book are correct in this case. What is implied in the Chapter, though not stated with sufficient clearness, is that if  $\frac{dp}{dy} = \infty$  leads to a solution which does not involve  $y$  in its expression, nothing is to be inferred whether it is singular or not. Then the proper test is  $\frac{d}{dx} \left( \frac{1}{p} \right) = \infty$ .

In this example we have

$$\frac{dp}{dy} = \infty \text{ gives } x^n = \infty ; \text{ no inference ;}$$

$$\frac{d}{dx} \left( \frac{1}{p} \right) = \infty \text{ gives } x^{-(n+1)} y^{-1} = \infty .$$

Hence  $x=0$ , provided  $n$  is between 0 and  $-1$ , or  $y=0$ .

Consider these separately :

First. Let  $n$  be between 0 and  $-1$ , and  $x=0$ . This is by the test a singular solution. Substituting it in the complete primitive we get  $y=c$ , which confirms this.

Second. Let  $y=0$ . This satisfies the differential equation; but from the fact that it comes from  $\frac{d}{dx} \left( \frac{1}{p} \right) = \infty$  we have no inference; from the fact that it does not come from  $\frac{dp}{dy} = \infty$  we have the inference that it is a particular integral: it corresponds to  $c=0$ .

There remains the case of  $x=0$  when  $n$  is between  $-1$  and  $-\infty$ . As this does not satisfy  $\frac{d}{dx} \left( \frac{1}{p} \right) = \infty$ , we infer that it is a particular integral. To prove this we have

$$c = y \epsilon^{-\frac{x^{n+1}}{n+1}}.$$

When  $x=0$  this gives, since  $1+n$  is negative,

$$c = \infty \text{ or } c = -\infty,$$

according as  $y$  is positive or negative. This is like Ex. 2 of Chap. VIII. Art. 8."

The remark made by Professor Boole in the above reply, that if  $\frac{dp}{dy} = \infty$  leads to a solution which does not involve  $y$  nothing is to be inferred...is important. It corrects the statement put too strongly in Chap. VIII. Art. 7, "All we can affirm is that if  $\frac{dp}{dy} = \infty$  gives a solution at all it will be a singular solution."

From Art. 8 onwards it seems assumed that a solution for which  $\frac{dy}{dc} = 0$  is always to count as a singular solution, even if it should coincide with a particular integral. This does not seem to have been quite the view of the former part of Chapter VIII.: see Arts. 5 and 6 of the Chapter.

In Ex. 3 of Art. 9 we read, "the second is obviously a singular solution." This means that since we have a solution which makes  $\frac{dp}{dy}$  infinite, we conclude that it is a singular solution.

So in Ex. 5 of Art. 11 we read, "is evidently a singular solution," when it seems better to say, "and is therefore a singular solution."

4. The additional matter relating to Chapter VIII. begins with another example which was to be placed at the close of Art. 3 of that Chapter.]

Ex. The differential equation

$$(\sqrt{x^2 + y^2 - m^2} - y) \frac{dy}{dx} - x = 0$$

has for its complete primitive

$$\sqrt{x^2 + y^2 - m^2} - y - c = 0.$$

Here  $\frac{d\phi}{dy} = \frac{y}{\sqrt{x^2 + y^2 - m^2}} - 1, \quad \frac{d\phi}{dx} = \frac{x}{\sqrt{x^2 + y^2 - m^2}},$

$$\frac{d\phi}{dc} = -1.$$

Hence  $\frac{dy}{dc} = \frac{\sqrt{x^2 + y^2 - m^2}}{y - \sqrt{x^2 + y^2 - m^2}}, \quad \frac{dx}{dc} = \frac{\sqrt{x^2 + y^2 - m^2}}{x}.$

Both  $\frac{dy}{dc}$  and  $\frac{dx}{dc}$  vanish then if

$$x^2 + y^2 - m^2 = 0.$$

This therefore is the singular solution and it satisfies both the tests, as both  $x$  and  $y$  are contained in its expression.

Of the partial tests

$$\frac{d\phi}{dc} = 0, \quad \frac{d\phi}{dx} = \infty, \quad \frac{d\phi}{dy} = \infty,$$

the first is not satisfied, the last two are satisfied.

The determination of  $c$  as a function of  $x$  by the solution of the equation  $\frac{df(x, c)}{dc} = 0$  is equivalent to determining what particular primitive has contact with the envelope at that point of the latter which corresponds to a given value of  $x$ .

One important remark yet remains. The elimination of  $c$  between a primitive  $y = f(x, c)$  and the derived equation  $\frac{dy}{dc} = 0$ , does not necessarily lead to a singular solution in the

sense above explained. For it is possible that the derived equation

$$\frac{df(x, c)}{dc} = 0$$

may neither on the one hand enable us to determine  $c$  as a function of  $x$ , so leading to a singular solution; nor, on the other hand, as an absolute constant, so leading to a particular primitive. Thus the particular primitive

$$y = e^{cx}$$

being given, the condition  $\frac{dy}{dc}$  gives

$$e^{cx} = 0,$$

whence  $c$  is  $+\infty$  if  $x$  be negative, and  $-\infty$  if  $x$  be positive. It is a dependent constant. The resulting solution  $y = 0$  does not then represent an envelope of the curves of particular primitives, nor strictly one of those curves. It represents a curve formed of branches from two of them. It is most fitly characterized as a particular primitive marked by a singularity in the mode of its derivation from the complete primitive.

All the foregoing observations and conclusions may be extended to the case of solutions derived from the condition  $\frac{dx}{dc} = 0$ .

5. We have seen that the equation  $\frac{dy}{dc} = 0$  may be satisfied by an absolutely constant value of  $c$ , so leading to a particular primitive and not a singular solution. In this case  $\psi(x+h, c)$  as well as  $\psi(x, c)$  would vanish, and the numerator of (9), instead of being the difference of a finite and an infinite quantity, would be the difference of two infinite and equal quantities. [See Chap. VIII. Art. 8.] It would not therefore be infinite. Hence we conclude that  $\frac{dp}{dy}$  would not become infinite for a particular primitive in the strict sense of that

term, i. e. for a solution derived from the complete primitive by giving to  $c$  an absolutely constant value.

This is one point of contrast between the conditions

$$\frac{dy}{dc} = 0, \quad \frac{dp}{dy} = \infty.$$

There is another not less important. As the numerator of (9) may become infinite not only when  $\psi(x, c) = 0$ , but also when  $\psi(x, c) = \infty$ , we see that a relation between  $y$  and  $x$  which makes  $\frac{dp}{dy}$  infinite will not necessarily satisfy the differential equation. On the other hand, it is not a particular primitive in the strict sense of that term.

Exactly in the same way the condition  $\frac{dx}{dc} = 0$ , as relating to the complete primitive, leads to the condition

$$\frac{d}{dx} \left( \frac{1}{p} \right) = \infty,$$

as relating to the differential equation, with the same points of difference in the respective applications.

Ex. Let  $\frac{dy}{dx} = my^{\frac{m-1}{m}}$ , and suppose  $m$  a positive constant greater than 1.

Here 
$$\frac{dp}{dy} = (m-1) \bar{y}^{\frac{1}{m}},$$

which becomes infinite when  $y = 0$ . As this involves  $y$  and satisfies the differential equation it is a singular solution.

To confirm this conclusion we may refer to the complete primitive

$$y = (x - c)^m,$$

which does not give  $y = 0$  for any particular value of  $c$ .

Now let  $m$  be a *positive* constant less than 1. We have still  $\frac{dp}{dy} = \infty$  when  $y = 0$ ; but this value of  $y$  no longer satis-

fies the differential equation. It is not a solution at all, nor would it result from the application of the condition  $\frac{dy}{dc} = 0$  to the complete primitive. The distinction of character of the two tests is here made manifest.

6. We may express the most important results of the foregoing investigations in the following theorem.

**THEOREM.** Every solution of a differential equation of the first order which is derived from the complete primitive by giving to  $c$  a variable value will, if it involve  $y$  in its expression, satisfy the condition

$$\frac{dp}{dy} = \infty ;$$

and if it involve  $x$ , the relation

$$\frac{d}{dx} \left( \frac{1}{p} \right) = \infty .$$

But relations satisfying these conditions will not necessarily be solutions of the differential equation.

In applying this theorem the following points must be carefully attended to.

1st. No conclusion can be drawn from the satisfying of the condition  $\frac{dp}{dy} = \infty$  when the relation in question does not contain  $y$  in its expression, nor from the satisfying of

$$\frac{d}{dx} \left( \frac{1}{p} \right) = \infty$$

when the relation in question does not involve  $x$  in its expression. For these conditions being respectively derived from  $\frac{dy}{dc} = 0$  and  $\frac{dx}{dc} = 0$  are subject to the same limitations in their application.

2ndly. It may be that  $\frac{dp}{dy}$  or  $\frac{d}{dx} \left( \frac{1}{p} \right)$  assumes for a particular relation between  $x$  and  $y$  the indefinite form  $\frac{0}{0}$ . In this

case we must seek by the development of its terms or by other known modes its true limiting value or values. Finite values will indicate particular primitives, infinite values singular solutions, and when such values emerge together out of the same relation between the variables, the solution will be a particular primitive possessing the geometrical properties of a singular solution. Its locus will be a particular curve enveloping other curves of the same family.

See Examples 2 and 3 of Chap. VIII. Art. 11.

We have seen that the conditions

$$\frac{dp}{dy} = \infty, \quad \frac{d}{dx} \left( \frac{1}{p} \right) = \infty$$

indicate in general the existence of a relation between  $c$  and  $x$  or  $c$  and  $y$ . And when that relation is such as to enable us to determine  $c$  as a continuous function of one of the variables, the corresponding solution of the differential equation is singular, and is geometrically represented by an envelope of the curves of primitives. But it may be, as we have seen in a particular example, that the relation does not determine  $c$  as a function of  $x$  or  $y$ ; but according to the language already used,  $c$  is a dependent constant, or in some other way different from the constant of an ordinary particular primitive. Let us examine in particular instances the kind of singularity which may hence arise.

Ex. 1. Given  $p = \frac{y \log y}{x}$ .

Here  $\frac{dp}{dy} = \frac{1}{x} (1 + \log y)$ .

This becomes infinite if  $x=0$ ; but this not involving  $y$  must be rejected. Again, it becomes infinite if  $y=0$ , and this proves to be a solution of the differential equation, the limiting value of the indeterminate function in the second member being 0 (Todhunter's *Differential Calculus*, Chap. x.). Now the complete primitive is  $y = e^{cx}$ , discussed in Art. 4. The constant  $c$  is there shewn to be dependent, the solu-

tion  $y=0$  emerging from the complete primitive by making  $c=-\infty$  if  $x$  be positive, and  $c=\infty$  if  $x$  be negative.

Ex. 2. Given  $\left(\frac{dy}{dx}\right)^2 - xy \frac{dy}{dx} + y^2 \log y = 0$ .

Here  $p = \frac{xy \pm y(x^2 - 4 \log y)^{\frac{1}{2}}}{2};$

therefore  $\frac{dp}{dy} = \frac{x \pm (x^2 - 4 \log y)^{\frac{1}{2}}}{2} \mp \frac{1}{(x^2 - 4 \log y)^{\frac{1}{2}}},$

and this is made infinite by  $y=0$  and by  $x^2 - 4 \log y = 0$ , i.e. by

$$y = 0, \quad y = e^{\frac{x^2}{4}}.$$

Both satisfy the differential equation.

Now the complete primitive is

$$y = e^{cx - c^2}.$$

We see at once therefore that the second of the above solutions is singular. The first however is deducible from the complete primitive by making  $c=\infty$  or  $c=-\infty$ , irrespectively of the *sign* or value of  $x$ , *provided only that  $x$  be finite*; not so however if  $x$  be infinite. The value of  $c$  is not therefore in the most absolute sense independent of that of  $x$ . If from the complete primitive we seek the singular solution by the condition  $\frac{dy}{dc} = 0$ , we get the two equation:

$$e^{cx - c^2} = 0, \quad x - 2c = 0.$$

The second of these determines  $c$  as a function of  $x$ , and leads to the second of the solutions obtained above. The first, though it does not determine  $c$  as a function of  $x$ , still expresses a *relation* between  $c$  and  $x$ , which is the ground of the fulfilment of the condition

$$\frac{dp}{dy} = \infty.$$

We may further notice a peculiarity arising from this relation. Supposing  $x$  finite and the solution  $y = 0$  a particular integral, it presents the singularity that it is the only case in which two particular integrals agree. We might in any complete primitive, by changing  $c$  into  $c^2$ , get two values of  $c$  for the same particular integral, but then it would be for *every* particular integral.

One negative character seems indeed to mark all the cases in which a solution involving  $y$  in its expression satisfies the condition  $\frac{dp}{dy} = \infty$ . It is that such solutions do not emerge from the complete primitive by the attributing of a single and absolutely constant value to  $c$ . The relation which makes  $\frac{dp}{dy}$  infinite satisfies the differential equation only because it satisfies the condition  $\frac{dy}{dc} = 0$ , and this implies a connexion between  $c$  and  $x$ , which is the ground of a real though it may be unimportant singularity in the solution itself.

At this point, then, the question arises, whether the term singular solution shall be confined to that class of solutions, the loci of which represent the envelopes of curves of primitives, or shall be extended to all solutions which, satisfying the condition  $\frac{dp}{dy} = \infty$ , indicate the existence of a relation between  $c$  and  $x$ , and possess an actual singularity arising from this source. While the all but universal consent of mathematicians is in favour of the former course, it is to be remembered that the question is solely one of *definition*. Not such is the question how singular solutions of the envelope species, or as would more generally be said true singular solutions, are to be distinguished from all other solutions. This we now propose to consider. The question is not an isolated one. It stands in close relation to a series of properties of singular solutions which admit of an orderly development.

*Discrimination of singular solutions of the envelope species.*

7. A negative test, which in the great majority of cases suffices for the present object, is suggested by the following consideration.

The differential equation determining  $\frac{dy}{dx}$  as a function of  $x$  and  $y$  determines also  $\frac{d^2y}{dx^2}$ ,  $\frac{d^3y}{dx^3}$ , *ad inf.*, and the knowledge of these enables us to construct in a developed form the complete primitive. See Chap. II. Art. 12.

The values of  $\frac{dy}{dx}$ ,  $\frac{d^2y}{dx^2}$ , &c. *ad inf.*, as derived from the differential equation, are the same as those derived from the complete primitive.

But a solution deduced from the condition  $\frac{dp}{dy} = \infty$  is only constructed so as to yield the same value of  $\frac{dy}{dx}$  as the given differential equation does. If it be of the envelope species, the curve it represents has in general no continuous contact with the curve of any particular primitive. It will not therefore *generally* yield the same values for  $\frac{d^2y}{dx^2}$ ,  $\frac{d^3y}{dx^3}$ , &c. as the differential equation does. It will not therefore generally satisfy the differential equations of an order higher than the first, which would be derived from the given equation by differentiation. Hence we have the following Proposition.

PROPOSITION. *If a relation which makes  $\frac{dp}{dy}$  infinite satisfy the given differential equation of the first order, but do not satisfy all the higher differential equations obtained from it, such solution will be singular and of the envelope species.*

Ex. 1. By comparison with its complete primitive we saw in Art. 5 that  $\frac{dy}{dx} = my^{\frac{m-1}{m}}$  has for a singular solution  $y = 0$  when  $m$  is a constant greater than 1.

We will first suppose  $m$  a fractional quantity greater than 1, and endeavour to deduce the character of the solution without making use of the complete primitive.

From the solution we have

$$\frac{d^2y}{dx^2} = 0, \quad \frac{d^3y}{dx^3} = 0, \quad \&c. \text{ ad inf.}$$

But from the differential equation

$$\frac{d^2y}{dx^2} = (m-1) y^{-\frac{1}{m}} \frac{dy}{dx} = m(m-1) y^{\frac{m-2}{m}},$$

and generally

$$\frac{d^r y}{dx^r} = m(m-1)\dots(m-r+1)y^{\frac{m-r}{m}}.$$

Hence, when  $r$  is less than  $m$ , the substitution of  $y = 0$  gives

$$\frac{d^r y}{dx^r} = 0$$

as before. But if  $r$  is greater than  $m$ , it gives

$$\frac{d^r y}{dx^r} = \infty.$$

We conclude that the solution is of the envelope species.

Secondly, suppose  $m$  a positive integer greater than 1.

In this case we find, when  $r$  is less than  $m$ , the same series of values as before; but for  $r = m$  we have

$$\frac{d^r y}{dx^r} = m(m-1)\dots 1,$$

and this also shews the solution to be of the envelope species.

Ex. 2. The differential equation

$$\frac{(y - xp)^2}{1 + p^2} = \frac{(x^2 + y^2)^2}{4}$$

is satisfied by

$$x^2 + y^2 = 4.$$

Is this a singular solution or a particular integral?

From the solution we find

$$\frac{dy}{dx} = -\frac{x}{y}, \quad \frac{d^2y}{dx^2} = -\frac{4}{y^3}.$$

From the differential equation we shall have

$$\frac{d^2y}{dx^2} = -\frac{(1 + p^2)^2 (x^2 + y^2)}{2(y - xp)},$$

substituting in which the value of  $\frac{dy}{dx}$ , obtained from the proposed solution, we find

$$\frac{d^2y}{dx^2} = -\frac{(x^2 + y^2)^2}{2y^3} = -\frac{8}{y^3}.$$

Now this differing from the value before obtained, we conclude that the solution is singular and of the envelope species.

And this result is verified by comparing the solution with the complete primitive

$$(x - c)^2 + (y - \sqrt{1 - c^2})^2 = 1.$$

As the test above exemplified is merely negative, it is insufficient. For it is conceivable that an enveloping curve should have an infinite order of contact with each of the curves which it envelopes, and this is also possible. Any test founded upon a comparison of the values of differential coefficients, any test therefore furnished by the *Differential Calculus*, would be insufficient for the discrimination of such cases.

Ex. 3. Given  $\frac{dy}{dx} = y (\log y)^2$ .

Here  $\frac{dp}{dy} = \infty$  gives  $y = 0$ , and this satisfies the differential equation.

From this solution we find

$$\frac{d^2y}{dx^2} = 0, \quad \frac{d^3y}{dx^3} = 0, \quad \&c. \text{ ad inf.}$$

From the differential equation we have

$$\frac{d^2y}{dx^2} = y \{(\log y)^4 + 2(\log y)^3\},$$

which consists of  $y$  multiplied by a rational and entire function of  $\log y$ . It is easy to see that all the higher differential coefficients of  $y$  hence derived will possess the same character. And all such vanish with  $y$ .

We can therefore neither affirm nor deny that the proposed solution is of the envelope species.

8. Before demonstrating a general Rule for the discrimination of solutions of this character, we shall notice certain of their properties which serve to indicate in what direction the Rule is to be sought. [See Chap. VIII. Art. 14.]

As the exact differential equation differs from the supposed given differential equation by having acquired a factor which the singular solution makes infinite, so the given differential equation may be said to differ from the corresponding exact one by containing a factor which the singular solution makes to vanish. If we knew that factor, we could by rejecting it reduce the given differential equation to a form in which it would no longer be satisfied by the singular solution. Now Poisson has shewn on a particular assumption, which does not however affect the principle of the demonstration, that this factor can be found when the singular solution is known. His demonstration is in substance as follows.

Let us represent the given singular solution of the differential equation by

$$u = 0,$$

$u$  being a given function of  $x$  and  $y$ . Then introducing  $u$  and

$x$  instead of  $y$  and  $x$  as variables, the differential equation after transformation will assume the form

$$\frac{du}{dx} = f(x, u).$$

Now this equation being satisfied by  $u=0$  and the first member vanishing, the second must also. Poisson now assumes, and the assumption must be carefully noted, this second member to be capable of being developed in ascending positive powers of  $u$ . Supposing it so developed, the differential equation becomes

$$\frac{du}{dx} = Au^\alpha + Bu^\beta + \&c.,$$

in which  $A, B, \dots$  are functions of  $x$ , and  $\alpha, \beta, \dots$  ascending positive indices.

Hence if  $u=0$  be a singular solution we have, putting  $p$  for  $\frac{du}{dx}$ ,

$$\frac{dp}{du} = A\alpha u^{\alpha-1} + B\beta u^{\beta-1} + \&c. = \infty.$$

But this demands that there should be at least one negative power of  $u$  in the development in the second member. Therefore  $\alpha-1$ , the lowest index, must be negative. Therefore  $\alpha$  being already positive must lie between 0 and 1.

We may give therefore to the transformed differential equation the form

$$\frac{du}{dx} = Qu^\alpha,$$

$\alpha$  being a positive fraction, and  $Q$  not vanishing with  $u$ . Hence, dividing by  $u^\alpha$ ,

$$u^{-\alpha} \frac{du}{dx} = Q,$$

or

$$\frac{1}{1-\alpha} \frac{d}{dx} u^{1-\alpha} = Q,$$

a differential equation which is *not* satisfied by  $u = 0$ , since  $u = 0$  gives  $u^{1-\alpha} = 0$ , and the first member vanishes while the second member does not vanish. In its present form then the equation is not satisfied by  $u = 0$ . We see also that the property of being satisfied by  $u = 0$  has been lost not in reality through a transformation, but through the rejection of an algebraic factor  $u^\alpha$  from the transformed equation. It has been shewn in the treatment of Clairaut's equation, how in the ascent by differentiation to an equation of a higher order a somewhat analogous effect is produced, the singular solution emerging out of a factor of that higher equation.

If we inquire what is essential in Poisson's demonstration, we shall find it to consist in that the transformed equation is of the form

$$\frac{du}{dx} = QU,$$

in which while  $Q$  neither vanishes nor becomes infinite when  $u = 0$ , the functions

$$U \text{ and } \int_0^u \frac{du}{U}$$

both vanish with  $u$ . The question whether  $U$  is of the form  $u^\alpha$  as Poisson supposes, or is not, is wholly immaterial. This will fully appear from the demonstration of the following theorem, which is in effect Poisson's freed from arbitrary assumptions.

9. PROPOSITION. *If  $u = 0$  be a solution of a differential equation of the first order between  $y$  and  $x$ , and*

$$\frac{du}{dx} = f(x, u)$$

*represent the form which that equation assumes when  $u$  and  $x$  are assumed as variables instead of  $y$  and  $x$ , then if  $f(x, u)$  be resolved into two factors  $Q, U$ , of which  $Q$  neither vanishes nor becomes infinite when  $u = 0$ , while the functions  $U$  and  $\int_0^u \frac{du}{U}$  both vanish when  $u = 0$ , then the differential equation can be reduced to a form in which it shall cease to be satisfied by  $u = 0$ .*

In the statement of this proposition  $x$  is supposed to be constant in the integration relative to  $u$ .

The differential equation after the transformation which introduces  $u$  and  $x$  as variables becomes

$$\frac{du}{dx} = QU.$$

Let

$$\int_0^u \frac{du}{U} = v,$$

so that  $v$  is in general a function of  $x$  and  $u$ , the form of which is known by integration when that of  $U$  is given. And again, transform the differential equation by making  $v$  and  $x$  the variables instead of  $u$  and  $x$ . We have

$$\left(\frac{dv}{dx}\right) = \frac{dv}{dx} + \frac{dv}{du} \frac{du}{dx},$$

in which  $\frac{dv}{dx}$  is the differential coefficient of  $v$  with respect to  $x$ , on the above hypothesis as to the constitution of  $v$  as a function of  $x$  and  $u$ , while  $\left(\frac{dv}{dx}\right)$  is the differential coefficient on the hypothesis that  $v$  is reduced to a function of  $x$  alone by the conversion of  $u$  into a function of  $x$ .

Since  $\frac{dv}{du} = \frac{1}{U}, \quad \frac{du}{dx} = QU,$

the above equation becomes

$$\left(\frac{dv}{dx}\right) = \frac{dv}{dx} + Q.$$

Now if  $u=0$  give  $v=0$  for all values of  $x$ , it will therefore give

$$\left(\frac{dv}{dx}\right) = 0,$$

and further,

$$\frac{dv}{dx} = \frac{d}{dx} \int_0^u \frac{du}{U} = 0,$$

since we are permitted to make  $u=0$  before effecting the differentiation with respect to  $x$ . Hence the equation reduces to

$$0 = Q.$$

And this is not satisfied, since by hypothesis  $Q$  does not vanish with  $u$ .

Hence if  $u=0$  make  $\int_0^u \frac{du}{U} = 0$ , the transformed differential equation will no longer have  $u=0$  for a solution.

COR. Assuming  $Q=1$ , which does not violate the hypothesis respecting  $Q$ , and gives

$$U = f(x, u),$$

we see that if

$$\frac{du}{dx} = f(x, u)$$

be satisfied by  $u=0$ , and if at the same time  $u=0$  gives

$$\int_0^u \frac{du}{f(x, u)} = 0,$$

the differential equation can be transformed so as to cease to admit of the solution  $u=0$ .

It is obvious however that it is best to assume  $Q$  so as to make the subsequent integration for determining  $v$  the simplest possible.

It is manifest that a solution which can thus be made to cease to satisfy the differential equation cannot be a particular primitive. For the complete primitive of the transformed differential equation which it does *not* satisfy is convertible into the complete primitive of the original differential equation which it does satisfy, merely by writing therein for  $v$  its expression as a function of  $x$  and  $y$ . It cannot therefore be a case of the complete primitive in any sense. It must be a singular solution of the envelope species.

The converse proposition still remains to be proved.

10. PROPOSITION. *If  $u=0$  be a singular solution of the envelope species of a differential equation of the first order, and if by assuming  $u$  and  $x$  as the variables, the differential equation is reduced to the form*

$$\frac{du}{dx} = f(x, u),$$

*then will*

$$\int_0^u \frac{du}{f(x, u)}$$

*become 0 when  $u=0$ .*

Let the complete primitive be represented by

$$F(x, u) = C,$$

then, since

$$\frac{dF(x, u)}{dx} + \frac{dF(x, u)}{du} \frac{du}{dx} = 0,$$

we have if for brevity we represent  $F(x, u)$  by  $F$ ,

$$\frac{du}{dx} = - \frac{\frac{dF}{dx}}{\frac{dF}{du}};$$

therefore

$$\int_0^u \frac{du}{f(x, u)} = - \int_0^u \frac{\frac{dF}{du}}{\frac{dF}{dx}} du.$$

Now  $u=0$  being a singular solution,  $F(x, 0)$  is not a constant; for if it were, the complete primitive would, on giving to  $C$  the constant value in question, yield  $u=0$  as a particular primitive. And this would equally be the case whether that constant were finite or infinite in value. We see then that  $F(x, 0)$  must be a function of  $x$ , and therefore  $\frac{dF(x, 0)}{dx}$  must either be a function of  $x$ , or a finite constant differing from 0; the latter if  $F(x, 0)$  be of the form  $ax + b$ , the former

if it be not of that form. Therefore the value of  $\frac{dF(x, u)}{dx}$  when  $u=0$ , since in this we are permitted to make  $u=0$  before differentiating with respect to  $x$ , will be a function of  $x$ , or a finite constant differing from 0.

Now it is manifest that in general

$$\int_0^u \frac{1}{\frac{dF}{dx}} \frac{dF}{du} du = H \int_0^u \frac{dF}{du} du,$$

where  $H$  is some value intermediate between the greatest and least values which  $\frac{1}{\frac{dF}{dx}}$  assumes within the limits of integration. When these limits are, as in the above case, infinitesimal, we have

$$H = \frac{1}{\frac{dF(x, 0)}{dx}}.$$

$$\begin{aligned} \text{Hence} \quad \int_0^u \frac{du}{f(x, u)} &= \frac{1}{\frac{dF(x, 0)}{dx}} \int_0^u \frac{dF}{du} du \\ &= \frac{1}{\frac{dF(x, 0)}{dx}} \{F(x, u) - F(x, 0)\}. \end{aligned}$$

But we have seen that  $\frac{dF(x, 0)}{dx}$  does not vanish. Hence its reciprocal, the first factor of the right-hand member of the above equation, does not become infinite. Again,

$$F(x, u) - F(x, 0)$$

vanishing when  $u=0$ , we have

$$\int_0^u \frac{du}{f(x, u)} = 0,$$

wher  $u$  is made infinitesimal as was to be shewn.

It will be observed that the previous general expression for  $\int_0^u \frac{du}{f(x, u)}$  becomes infinite if  $u=0$  is a particular integral.

For then,  $F(x, 0)$  being a constant,  $\frac{dF(x, 0)}{dx}$  vanishes, while  $F(x, u) - F(x, 0)$  does not vanish so long as  $u$  differs by however small a quantity from 0.

These propositions form the ground of the following Rule for the discrimination of singular solutions of the envelope species from all others.

11. RULE. The proposed solution being represented by  $u=0$ , let the differential equation, transformed by making  $u$  and  $x$  the variables, be

$$\frac{du}{dx} + f(x, u) = 0.$$

Determine as a function of  $x$  and  $u$  the integral

$$\int_0^u \frac{du}{U},$$

in which  $U$  is either equal to  $f(x, u)$ , or to  $f(x, u)$  deprived of any factor which neither vanishes nor becomes infinite when  $u=0$ . If that integral tend to 0 with  $u$  the solution is singular.

Ex. 1. Determine whether  $y=0$  is a singular solution or particular integral of the differential equation

$$\frac{dy}{dx} = y (\log y)^2.$$

Here, since  $u=y$ , no preliminary transformation is needed.

We have 
$$\int_0^y \frac{dy}{y (\log y)^2} = -\frac{1}{\log y},$$

which tends to 0 with  $y$ . Hence the solution is singular.

To verify this we observe that the complete primitive is

$$y = e^{\frac{1}{e^{-x}}},$$

and this cannot be reduced to  $y=0$  by giving any constant value to  $c$ .

We have seen in Art. 7 that the test which is founded upon the comparison of differential coefficients does not suffice to characterize the above solution.

Ex. 2. The equation  $\frac{dy}{dx} = \frac{y \log y}{x}$  is satisfied by  $y = 0$ . Is this solution singular or particular?

Here also no transformation is required. We have, rejecting the factor  $\frac{1}{x}$  which neither vanishes nor becomes infinite when  $y = 0$ ,

$$\begin{aligned} \int_0^y \frac{dy}{y \log y} &= \log \log y - \log \log 0 \\ &= \log \frac{\log y}{\log 0}, \end{aligned}$$

and this being infinite, however small  $y$  may be, may properly be said to tend to infinity as  $y$  tends to 0. The solution is therefore particular.

It will perhaps appear at first sight as if in the above example we ought to write

$$\log \frac{\log y}{\log 0} = \log 1 = 0$$

when  $y$  is made equal to 0. But the course of the demonstration shews that the value of the definite integral must be first obtained on the hypothesis that  $u$  (in this case replaced by  $y$ ) is finite, and then the limiting value which its expression approaches to, as  $u$  approaches to 0, be sought. And in this case, since for all finite values of  $u$  however small the integral is infinite, its limiting value is infinite.

The complete primitive in the above case is

$$y = e^{cx},$$

and the nature of the solution  $y = 0$  has already been discussed in Art. 4.

*History of the Theory of Singular Solutions.*

12. It is remarkable that while the theory of enveloping curves and surfaces was at once founded and developed by Leibnitz in 1692—4\*, the corresponding theory of the singular solutions of differential equations has been of very slow growth. The existence of these solutions was first recognised in 1715 by Brook Taylor; it was scarcely more than recognised by Clairaut in 1734. Euler, in a special memoir, entitled *Exposition de quelques Paradoxes dans le Calcul Integral*, published in the Memoirs of the Academy of Berlin for 1756, first made them a direct object of investigation; but the foundations of their true theory were only laid in 1768 in his *Institutiones Calculi Integralis*. Laplace, Lagrange, Legendre, Poisson, Cauchy, and De Morgan have in various ways developed and extended that theory; but there has been so remarkable a want of unity and connexion in this long series of researches, that important portions of the theory appearing in a too isolated form have been neglected, forgotten, and rediscovered. I purpose here to give a brief account of what seems most characteristic, rather than of what is most original in their several researches; for the germs of nearly all subsequent discoveries on the subject are to be found in the great work of Euler.

Taylor and Clairaut appear to have been led by accident to the noticing of singular solutions; the former while directly occupied on the solution of differential equations, the latter while discussing a remarkable class of problems relating to the connecting properties of different branches of the same curve. Taylor gave them the name singular, while Clairaut, and Euler too in his memoir, regarded them as a species of paradox, not merely from their non-inclusion in the general integral, but from the mode of their discovery through a process of differentiation. The memoir of Euler, though it sheds no light on the real nature of these solutions, contains

\* *Acta Eruditorum*, 1692, p. 168; 1694, p. 311. *Opera*, Tom. III. pp. 264, 296.

*Methodus Incrementorum*, p. 26.

*Mémoires de l'Académie des Sciences*, 1734, p. 209.

an interesting theorem concerning their connexion with the form of the differential equation, viz. If this equation can be brought to the form

$$Vdz = Z(Pdx + Qdy),$$

in which  $z$  is a function of  $x$  and  $y$ , and  $Z$  of  $z$ , then will

$$Z = 0$$

be a singular solution. In his *Institutiones Calculi Integralis*, Tom. I. p. 393, however, Euler gives a rule which is the counterpart of that of Cauchy. [See Chap. VIII. Art. 12.] He shews that if  $u = 0$  be a particular integral, and if the differential equation be reduced to the form

$$\frac{du}{dx} = \phi(x, u),$$

then

$$\int_0^u \frac{du}{\phi(x, u)} = \infty.$$

The limits of integration are here supplied. The reasoning, which is not fully developed, is the following. From the transformed equation we have

$$dx = \frac{du}{\phi(x, u)}.$$

Hence

$$x = C + \int \frac{du}{\phi(x, u)},$$

$$\frac{x}{C} = 1 + \frac{1}{C} \int \frac{du}{\phi(x, u)}.$$

If this be satisfied by a solution involving  $x$  and  $y$ , and if that solution be a particular integral, then on putting for  $x$  its value in terms of  $u$  and integrating, the above equation will be satisfied by giving some particular constant value to  $C$ . But if the supposed particular integral be  $u = 0$ , then  $x$  and  $u$  being independent, we may perform the integration with respect to  $u$  as if  $x$  were constant. The resulting equation cannot be free from  $x$  unless  $C$  be infinite, and then it

will evidently not be satisfied unless  $\int \frac{du}{\phi(x, u)}$  be infinite. We infer then that this is a necessary condition in order that  $u = 0$  may be a particular integral.

This is Euler's fundamental theorem, and from this, by means of an hypothesis agreeing with that of Poisson concerning the form of the transformed differential equation, he arrives at the condition

$$\frac{dp}{dy} = \infty.$$

[In the passage to which Professor Boole refers, Euler does not undertake to discuss the nature of *any* solution, but only of a solution of the form  $x = \text{constant}$ . On his page 408 Euler proceeds to discuss the nature of *any* solution. Professor Boole seems to me to attribute too much to Euler. For the convenience of those who wish to examine the original, I will give the reference to the passages in the later editions of Euler's *Institutiones Calculi Integralis*: Vol. I. pages 343 and 355 of the edition of 1792; Vol. I. pages 342 and 354 of the edition of 1824.]

Laplace in the Memoirs of the French Academy for 1772, p. 343, established the tests

$$\frac{dp}{dy} = \infty, \quad \frac{d}{dx} \left( \frac{1}{p} \right) = \infty,$$

and shewed their respective uses. He established also the test which consists in the comparison of differential coefficients, and he supposes it universal. He adopts the hypothesis of his predecessors as to the forms of expansion, but with some recognition of its insufficiency.

Lagrange in the Memoirs of the Academy of Berlin for 1774, p. 197, and 1779, p. 121, appears first to have developed the theory of singular solutions in its two forms of derivation from the complete primitive and derivation from the differential equation, and to have established the essential connexion of these. But supposing the differential equation to be expressible in the rational form

$$F(x, y, p) = 0,$$

and employing the differential coefficients of  $F(x, y, p)$  instead of those of  $p$  he was led to sacrifice rigour to symmetry. One of his results has often since been adopted as a test of singular solutions. It may be thus stated.

PROP. A singular solution makes the *general* value of  $\frac{d^2y}{dx^2}$ , deduced from the differential equation in its rational and integral expression, to assume the form  $\frac{0}{0}$ .

[The demonstration is given in Chap. VIII. Art. 14.]

This ambiguity of value of  $\frac{d^2y}{dx^2}$  is evidently but an expression of the fact that the contact of a curve of the complete primitive and that of the singular solution is not in general of the second order.

The result given in equation (5) of Chap. VIII. Art. 14 has also been adopted as the test of singular solutions.

The researches of Poisson and Cauchy have already been noticed. It is certainly remarkable that the final test to which Cauchy's analysis led should be essentially the same as that which had been discovered by Euler so long before.

Professor De Morgan has thrown an important light upon the nature of the conditions

$$\frac{dp}{dy} = \infty, \quad \frac{dp}{dx} = \infty,$$

which are fulfilled by all singular solutions in the expression of which  $x$  and  $y$  are both involved. He has shewn that any relation between  $x$  and  $y$  which satisfies these conditions will satisfy the differential equation unless it make  $\frac{d^2y}{dx^2}$ , as derived from the differential equation, infinite; that it *may* satisfy the differential equation even if it make  $\frac{d^2y}{dx^2}$  infinite; lastly, that

if it do not satisfy the differential equation, the curve it represents is a locus of points of infinite curvature, usually cusps, in the curves of complete primitives.

The proof is as follows :

Let  $p = \phi(x, y)$

be the differential equation. Then the proposed conditions are

$$\frac{d\phi(x, y)}{dy} = \infty, \quad \frac{d\phi(x, y)}{dx} = \infty,$$

therefore by differentiation,

$$\frac{d^2\phi}{dx dy} + \frac{d^2\phi}{dy^2} \frac{dy}{dx} = 0, \quad \frac{d^2\phi}{dx^2} + \frac{d^2\phi}{dx dy} \frac{dy}{dx} = 0,$$

whence we have

$$\frac{dy}{dx} = - \frac{\frac{d^2\phi}{dx dy}}{\frac{d^2\phi}{dy^2}} = - \frac{\frac{d^2\phi}{dx^2}}{\frac{d^2\phi}{dx dy}}.$$

These are two equivalent expressions for the same value of  $\frac{dy}{dx}$ . The question now is, under what circumstances this value of  $\frac{dy}{dx}$  will satisfy the differential equation.

Now from that equation we have by differentiation

$$\frac{d^2y}{dx^2} = \frac{d\phi}{dx} + \frac{d\phi}{dy} \frac{dy}{dx},$$

whence

$$\frac{dy}{dx} = \frac{\frac{d^2y}{dx^2} - \frac{d\phi}{dx}}{\frac{d\phi}{dy}}.$$

If then  $\frac{d^2y}{dx^2}$  be finite we have, since  $\frac{d\phi}{dx}$  and  $\frac{d\phi}{dy}$  are both infinite,

$$\frac{dy}{dx} = - \frac{\frac{d\phi}{dx}}{\frac{d\phi}{dy}},$$

and this by the rule for the evaluation of fractions of the form  $\frac{\infty}{\infty}$  is equivalent to the value in either of its forms before obtained for  $\frac{dy}{dx}$ . Hence, any relation which satisfies the given conditions and makes  $\frac{d^2y}{dx^2}$  finite, will satisfy the differential equation.

And the same result holds even if  $\frac{d^2y}{dx^2}$  be infinite, provided that  $\frac{d^2y}{dx^2} \div \frac{d\phi}{dy}$  vanish.

Lastly, as when this result does not hold, the failure is due to the infinite value of  $\frac{d^2y}{dx^2}$ , we see that the line in which the locus of the proposed relation intersects the curves of primitives will be a locus of their points of infinite curvature.

[Transactions of the *Cambridge Philosophical Society*, Vol. IX. Part II.]

Legendre's Memoir of 1790 throws but little light upon the subject of this Chapter. But it exhibits the theory of the singular solutions of differential equations of the higher orders, both ordinary and partial, in a form of great beauty, and will be noticed in the proper places.

## CHAPTER XXII.

## ADDITIONS TO CHAPTER IX.

1. By successive application of the second theorem of Chap. IX. Art. 13, a linear equation of the  $n^{\text{th}}$  order may be reduced to one of the  $(n-r)^{\text{th}}$  order, if  $r$  distinct integrals of what the given equation deprived of its second term would be are known.

The reduction may however be effected immediately by the method of the variation of parameters. In this and in most general investigations connected with differential equations great advantages in point of brevity and of the power of expression are gained by the employment of the symbol of summation  $\Sigma$ , and of the language of determinants. I shall exemplify this here.

Suppose the given equation to be

$$\frac{d^n y}{dx^n} + A_1 \frac{d^{n-1} y}{dx^{n-1}} + A_2 \frac{d^{n-2} y}{dx^{n-2}} \dots + A_n = X \dots \dots (1),$$

and let  $y_1, y_2, \dots y_r$  be  $r$  particular values of  $y$ , satisfying the equation

$$\frac{d^n y}{dx^n} + A_1 \frac{d^{n-1} y}{dx^{n-1}} + A_2 \frac{d^{n-2} y}{dx^{n-2}} \dots + A_n = 0 \dots \dots (2).$$

Thus

$$y = c_1 y_1 + c_2 y_2 \dots + c_r y_r$$

is a solution of the latter equation including these particular solutions. We shall represent this by

$$y = \Sigma c_i y_i \dots \dots \dots (3),$$

and regarding the quantities  $c_1, c_2, \dots c_r$ , represented here by

$c_i$  as variable parameters, shall seek to determine them so that the above value of  $y$  may satisfy the equation given.

These  $r$  parameters, enabling us to satisfy  $r - 1$  arbitrary conditions, besides satisfying the differential equation, we may choose these so that

$$\frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots, \frac{d^{r-1}y}{dx^{r-1}}$$

may be the same *in form* as if  $c_1, c_2, \dots, c_r$  were constant. Now from (3)

$$\frac{dy}{dx} = \sum c_i \frac{dy_i}{dx} + \sum y_i \frac{dc_i}{dx},$$

whence

$$\frac{dy}{dx} = \sum c_i \frac{dy_i}{dx},$$

provided that the condition

$$\sum y_i \frac{dc_i}{dx} = 0$$

be satisfied. Differentiating the first of these equations, we find in the same way that

$$\frac{d^2y}{dx^2} = \sum c_i \frac{d^2y_i}{dx^2},$$

provided that the condition

$$\sum \frac{dy_i}{dx} \frac{dc_i}{dx} = 0$$

be satisfied. And thus continuing we see that the system of  $r$  equations

$$y = \sum c_i y_i, \quad \frac{dy}{dx} = \sum c_i \frac{dy_i}{dx}, \dots, \frac{d^{r-1}y}{dx^{r-1}} = \sum c_i \frac{d^{r-1}y_i}{dx^{r-1}} \dots \dots (4),$$

will hold true provided that the  $r - 1$  conditions

$$\sum y_i \frac{dc_i}{dx} = 0, \quad \sum \frac{dy_i}{dx} \frac{dc_i}{dx} = 0, \dots, \sum \frac{d^{r-2}y_i}{dx^{r-2}} \frac{dc_i}{dx} = 0 \dots \dots (5),$$

be satisfied. In each of these equations the symbol  $\Sigma$  is to be interpreted by giving to  $i$  the successive values 1, 2, ...  $r$ , and taking the sum of the results.

Differentiating the last of the equations (4), we have

$$\frac{d^r y}{dx^r} = \Sigma c_i \frac{d^r y_i}{dx^r} + \Sigma \frac{d^{r-1} y_i}{dx^{r-1}} \frac{dc_i}{dx}.$$

As we cannot impose the condition that the last term of this equation shall vanish, let  $z$  represent its unknown value, then

$$\frac{d^r y}{dx^r} = \Sigma c_i \frac{d^r y_i}{dx^r} + z \dots\dots\dots (6).$$

Now the system of equations (5), together with

$$\Sigma \frac{d^{r-1} y_i}{dx^{r-1}} \frac{dc_i}{dx} = z,$$

constitute a system of  $r$  simple algebraic equations determining by solution the  $r$  quantities

$$\frac{dc_1}{dx}, \frac{dc_2}{dx}, \dots \frac{dc_r}{dx}$$

in terms of their coefficients and of  $z$ , and therefore in terms of  $x$  and  $z$ , since the coefficients are known as functions of  $x$ . It is evident also that as the second members of all the equations but one vanish, and the second member of that is  $z$ , the values so determined will be of the form

$$\frac{dc_1}{dx} = X_1 z, \quad \frac{dc_2}{dx} = X_2 z, \quad \dots \quad \frac{dc_r}{dx} = X_r z,$$

$X_1, X_2, \dots X_r$  being known functions of  $x$ . Thus the  $r$  unknown quantities  $\frac{dc_1}{dx}, \dots \frac{dc_r}{dx}$  are made to depend upon only one unknown quantity, viz.  $z$ . It remains then to determine  $z$ .

For this purpose we must complete the expression of the differential coefficients of  $y$ , and substitute in the given differential equation, and then seek to satisfy that equation.

Now differentiating (6) we have

$$\begin{aligned}\frac{d^{r+1}y}{dx^{r+1}} &= \sum c_i \frac{d^{r+1}y_i}{dx^{r+1}} + \sum \frac{d^r y_i}{dx^r} \frac{dc_i}{dx} + \frac{dz}{dx} \\ &= \sum c_i \frac{d^{r+1}y_i}{dx^{r+1}} + \sum \left( \frac{d^r y_i}{dx^r} X_i \right) z + \frac{dz}{dx}\end{aligned}$$

on substituting for  $\frac{dc_i}{dx}$  the value  $X_i z$  as above determined.

We observe that the coefficient of  $z$  is here a known function of  $x$ . If we differentiate this equation and in the result substitute as above for  $\frac{dc_i}{dx}$ , we shall have a result of the form

$$\frac{d^{r+2}y}{dx^{r+2}} = \sum c_i \frac{d^{r+2}y_i}{dx^{r+2}} + Lz + M \frac{dz}{dx} + \frac{d^2z}{dx^2},$$

$L$  and  $M$  being known functions of  $x$ . Ultimately then we have

$$\frac{d^n y}{dx^n} = \sum c_i \frac{d^n y_i}{dx^n} + Pz + Q \frac{dz}{dx} \dots\dots + \frac{d^{n-r}z}{dx^{n-r}}.$$

Thus, while  $y$  and the differential coefficients of  $y$  up to the  $(r-1)^{\text{th}}$  are of the same form as if  $c_1, c_2, \dots c_r$  were constant, the succeeding ones differ in containing an additional portion consisting of  $z$ , and differential coefficients of  $z$  multiplied by known functions of  $x$ . The result of substitution of these values in the given differential equation will therefore consist also of two classes of terms, viz. terms under the sign of summation, which will be the same in form as if  $c_1, c_2, \dots c_r$  were constant, and terms involving the differential coefficients of  $z$  up to the  $(n-r)^{\text{th}}$ , with multipliers which are known functions of  $x$ . We shall in fact have

$$\begin{aligned}\sum c_i \left( \frac{d^n y_i}{dx^n} + A_1 \frac{d^{n-1} y_i}{dx^{n-1}} + A_2 \frac{d^{n-2} y_i}{dx^{n-2}} \dots\dots + A_n \right) \\ + \frac{d^{n-r}z}{dx^{n-r}} + R \frac{d^{n-r-1}z}{dx^{n-r-1}} \dots\dots + S = X.\end{aligned}$$

Now  $y_i$  being by hypothesis an integral of (2), the first line of the above equation vanishes, and there remains the linear equation of the  $(n-r)^{\text{th}}$  order

$$\frac{d^{n-r}z}{dx^{n-r}} + R \frac{d^{n-r-1}z}{dx^{n-r-1}} \dots\dots + S = X.$$

Supposing  $z$  hence determined, we have in general

$$c_i = \int X_i z dx,$$

and hence

$$y = y_1 \int X_1 z dx + y_2 \int X_2 z dx \dots\dots + y_r \int X_r z dx,$$

and as  $z$  will have  $n-r$  distinct values, each involving an arbitrary constant, the above equation will furnish  $n-r$  distinct values of  $y$ , each involving an arbitrary constant. It is to be observed that no arbitrary constant need be added in the integration of the terms  $X_i z dx$ , for the effect of such addition would only be to reproduce the known integrals  $c_i y_i$ . In this way, however, the equation would represent the *general* integral of the differential equation given.

2. Let us examine the form of the result in the particular case in which  $r = n-1$ .

Here we have

$$\frac{d^m y}{dx^m} = \sum c_i \frac{d^m y_i}{dx^m}$$

from  $m = 0$  to  $m = n-2$ , then

$$\frac{d^{n-1} y}{dx^{n-1}} = \sum c_i \frac{d^{n-1} y_i}{dx^{n-1}} + z,$$

$$\frac{d^n y}{dx^n} = \sum c_i \frac{d^n y_i}{dx^n} + \sum \left( X_i \frac{d^{n-1} y_i}{dx^{n-1}} \right) z + \frac{dz}{dx}.$$

Accordingly the differential equation for  $z$  will be

$$\frac{dz}{dx} + \Sigma \left( X_i \frac{d^{n-1}y_i}{dx^{n-1}} \right) z + A_1 z = X \dots \dots \dots (7).$$

Now the equations for determining

$$\frac{dc_1}{dx}, \quad \frac{dc_2}{dx}, \dots \frac{dc_{n-1}}{dx}$$

become on putting  $X_i z$  for  $\frac{dc_i}{dx}$ , and writing for brevity  $y'_i$  for  $\frac{dy_i}{dx}$ ,  $y''_i$  for  $\frac{d^2y_i}{dx^2}$ , &c.,

$$y_1 X_1 + y_2 X_2 \dots + y_{n-1} X_{n-1} = 0,$$

$$y'_1 X_1 + y'_2 X_2 \dots + y'_{n-1} X_{n-1} = 0,$$

.....

$$y_1^{(n-3)} X_1 + y_2^{(n-3)} X_2 \dots + y_{n-1}^{(n-3)} X_{n-1} = 0,$$

$$y_1^{(n-2)} X_1 + y_2^{(n-2)} X_2 \dots + y_{n-1}^{(n-2)} X_{n-1} = 1.$$

Whence, by the theory of determinants,

$$X_1 = \frac{1}{M} \frac{dM}{dy_1^{(n-2)}}, \dots X_{n-1} = \frac{1}{M} \frac{dM}{dy_{n-1}^{(n-2)}},$$

$M$  standing for the determinant

$$\begin{vmatrix} y_1, & y_2, & \dots & y_{n-1} \\ \dots & \dots & \dots & \dots \\ y_1^{(n-2)}, & y_2^{(n-2)}, & \dots & y_{n-1}^{(n-2)} \end{vmatrix}$$

Now the determinant is ultimately a function of  $x$ ; and such indeed that

$$\Sigma \left( X_i \frac{d^{n-1} y_i}{dx^{n-1}} \right) = \frac{1}{M} \frac{dM}{dx}.$$

For

$$\begin{aligned} \frac{dM}{dx} &= \Sigma \frac{dM}{dy_i} \frac{dy_i}{dx} + \Sigma \frac{dM}{dy_i'} \frac{dy_i'}{dx} \dots + \Sigma \frac{dM}{dy_i^{(n-2)}} \frac{dy_i^{(n-2)}}{dx} \\ &= \Sigma \frac{dM}{dy_i} y_i' + \Sigma \frac{dM}{dy_i'} y_i'' \dots + \Sigma \frac{dM}{dy_i^{(n-2)}} y_i^{(n-1)} \dots \dots (8). \end{aligned}$$

Now  $M$  being homogeneous and of the first degree with respect to the quantities  $y_1, y_2, \dots, y_{n-2}$ , we have

$$\Sigma \frac{dM}{dy_i} y_i = M.$$

Hence  $\Sigma \frac{dM}{dy_i} y_i'$  is what  $M$  becomes when in its expression  $y_1, y_2, \dots, y_{n-1}$  are changed into  $y_1', y_2', \dots, y_{n-1}'$ , therefore it is what  $M$  becomes when two of its rows of elements become identical; therefore it vanishes. In like manner all the other sums in (8) vanish excepting the last, for  $y_1^{(n-1)}, \dots, y_{n-1}^{(n-1)}$  is not a row of elements of the determinant  $M$ . Thus we have

$$\Sigma \frac{dM}{dy_i^{(n-2)}} y_i^{(n-1)} = \frac{dM}{dx}.$$

Hence

$$\Sigma X_i y_i^{(n-1)} = \Sigma \frac{1}{M} \frac{dM}{dy_i^{(n-2)}} y_i^{(n-1)} = \frac{1}{M} \frac{dM}{dx}.$$

Thus the equation (7) becomes

$$\frac{dz}{dx} + \left( \frac{1}{M} \frac{dM}{dx} + A_1 \right) z = X;$$

therefore 
$$z = \frac{1}{M} e^{-\int A_1 dx} \int M e^{\int A_1 dx} X dx.$$

Hence, since

$$\frac{dc_i}{dx} = X_i z = \frac{1}{M} \frac{dM}{dy_i^{(n-2)}} z,$$

whence

$$c_i = \int \frac{1}{M} \frac{dM}{dy_i^{(n-2)}} z dx,$$

we have

$$y = \sum y_i \int \frac{1}{M} \frac{dM}{dy_i^{(n-2)}} z dx,$$

$z$  being given above.

In the case of  $X = 0$ , we have

$$z = \frac{C}{M} e^{-\int A_1 dx},$$

whence

$$y = \sum y_i \int \frac{C}{M^2} \frac{dM}{dy_i^{(n-2)}} e^{-\int A_1 dx} dx.$$

## CHAPTER XXIII.

## ADDITIONS TO CHAPTER X.

1. THE theory of singular solutions of differential equations of the higher orders has been presented in the most complete form which it has yet received by Legendre. (*Mémoires de l'Académie Royale des Sciences*, 1790, p. 218.) He determines first the possible forms of these solutions considered as emerging from the complete primitive by the variations of its arbitrary constants, and secondly the theory of their derivation from the differential equation itself. I shall follow the same order, and shall in the end endeavour to point out in what respect Legendre's theory may be regarded as complete, and in what respect it is imperfect.

Suppose the differential equation to be of the  $n^{\text{th}}$  order, and let it when solved with respect to the highest differential coefficient of  $y$  be represented by

$$y_n = \phi(x, y, y_1, y_2, \dots y_{n-1}) \dots\dots\dots (1),$$

in which, for brevity,

$$y_1 = \frac{dy}{dx}, \quad y_2 = \frac{d^2y}{dx^2}, \quad \dots \quad y_n = \frac{d^ny}{dx^n}.$$

Let also its complete primitive, solved with respect to  $y$ , be represented by

$$y = f(x, a_1, a_2, \dots a_n) \dots\dots\dots (2),$$

$a_1, a_2, \dots a_n$  being the arbitrary constants of the solution. If we differentiate (2) with respect to  $x$ , regarding  $a_1, a_2, \dots a_n$  no longer as constants but as functions of  $x$ , so to be determined as to leave the expressions for  $y_1, y_2, \dots y_n$  as functions

In this system the coefficients of

$$\frac{da_1}{dx}, \frac{da_2}{dx}, \dots \frac{da_n}{dx}$$

are known functions of  $x, a_1, a_2, \dots a_n$  when the form of  $f$  is known.

Eliminating

$$\frac{da_1}{dx}, \frac{da_2}{dx}, \dots \frac{da_n}{dx},$$

we have a relation between  $x, a_1, a_2, \dots a_n$ ; and this relation, with the given complete primitive and the first  $n-1$  of the derived and reduced equations, viz., with

$$y=f, \quad y_1=\frac{df}{dx}, \quad y_2=\frac{d^2f}{dx^2}, \dots y_{n-1}=\frac{d^{n-1}f}{dx^{n-1}},$$

will enable us to eliminate  $a_1, a_2, \dots a_n$ , and to obtain a relation of the form

$$\psi \left( x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots \frac{d^{n-1}y}{dx^{n-1}} \right) = 0 \dots\dots\dots (5).$$

This is a differential equation of the  $(n-1)^{\text{th}}$  order. It differs in its origin from the given differential equation, in that a *new* relation between  $x, a_1, a_2, \dots a_n$  has been employed in place of the  $n^{\text{th}}$  equation, derived by differentiation from the complete primitive, for the elimination of the constants.

The differential equation of the  $(n-1)^{\text{th}}$  order thus obtained has an integral expressing  $y$  in terms of  $x$ , and  $n-1$  arbitrary constants. This is the most general form of a singular solution of the differential equation.

It is possible that the elimination of  $a_1, a_2, \dots a_n$  may lead to a resulting differential equation which, instead of being of the order  $n-1$ , is of the order  $n-2, n-3$ , &c. The complete integral of such equation would be a singular solution of the differential equation. These possible types of solutions are distinguished by Legendre according to the number of arbitrary constants which they contain. A solu-

tion containing  $n - 1$  arbitrary constants is called by him a singular solution of the first order; one containing  $n - 2$  arbitrary constants a singular solution of the second order, and so on.

Adopting this language we might term the complete primitive a singular solution of the order 0.

Lastly, any relation between  $x$  and  $y$ , which satisfies the given differential equation, will constitute a particular case, either of the complete primitive or of one of the general forms of singular solutions above defined. In the case of differential equations of the first order it is seen that no arbitrary constant can appear in the expression of the singular solution.

Ex. The equation

$$y - x \frac{dy}{dx} + \frac{1}{2} x^2 \frac{d^2y}{dx^2} - \left( \frac{d^2y}{dx^2} \right)^2 - \left( \frac{dy}{dx} - x \frac{d^2y}{dx^2} \right)^2 = 0$$

has for its complete primitive

$$y = \frac{ax^2}{2} + bx + a^2 + b^2 \dots\dots\dots(6),$$

required its singular solution.

Proceeding as above, we find on the hypothesis of  $a$  and  $b$  being variable parameters, the same formal expressions for  $\frac{dy}{dx}$ ,  $\frac{d^2y}{dx^2}$  as if those parameters were constant, viz.

$$\left. \begin{aligned} \frac{dy}{dx} &= ax + b \\ \frac{d^2y}{dx^2} &= a \end{aligned} \right\} \dots\dots\dots(7),$$

provided that the variation of  $a$  and  $b$  be such as to satisfy the conditions

$$\left. \begin{aligned} \left( \frac{x^2}{2} + 2a \right) \frac{da}{dx} + (x + 2b) \frac{db}{dx} &= 0 \\ x \frac{da}{dx} + \frac{db}{dx} &= 0 \end{aligned} \right\} \dots\dots\dots(8).$$

Eliminating hence  $\frac{da}{dx}$  and  $\frac{db}{dx}$ , we have

$$2a - \frac{x^2}{2} - 2bx = 0.$$

And from this, the complete primitive, and the first of the derived equations (7) eliminating  $a$  and  $b$ , we find

$$\left(\frac{dy}{dx}\right)^2 + \left(\frac{x^3}{2} + x\right)\frac{dy}{dx} - (1 + x^2)y - \frac{x^4}{16} = 0 \dots\dots(9).$$

This is the differential equation of the first order, by the solution of which the most general form of the singular solutions of the given differential equation will be determined.

Reducing it to the form

$$\frac{4dy + (2x + x^3)dx}{(16y + 4x^2 + x^4)^{\frac{1}{2}}} = (1 + x^2)^{\frac{1}{2}}dx,$$

and integrating, we find

$$(16y + 4x^2 + x^4)^{\frac{1}{2}} = x(1 + x^2)^{\frac{1}{2}} + \log\{x + \sqrt{(1 + x^2)}\} + C.$$

This then is the general expression for the singular solutions of the given differential equation. We see that it involves in its expression *one* arbitrary constant.

The differential equation (9) may properly be termed a singular first integral of the given differential equation. The singular first integral (9) has itself also a singular solution, viz.

$$y = -\frac{1}{4}x^2 - \frac{1}{16}x^4;$$

but this is not a solution of the original differential equation. Nor have we any right to expect that it should be so. A singular solution of a differential equation of the first order does not necessarily satisfy the differential equations of higher orders derived from that equation, Chapter XXII. Art. 7.

2. It remains to establish the theory of the derivation of the singular solution from the differential equation without the mediation of the complete primitive.

Resuming the differential equation in its reduced form (1), and representing its second member by  $\phi$ , suppose an infinitesimal variation given to the arbitrary constants of its complete primitive, and let the symbol  $\delta$  be used to denote the corresponding derived variations of  $y, y_1, \dots y_n$ . Then we have

$$\delta y_n = \frac{d\phi}{dy} \delta y + \frac{d\phi}{dy_1} \delta y_1 \dots + \frac{d\phi}{dy_{n-1}} \delta y_{n-1}.$$

$$\text{But } \delta y_1 = \frac{\delta dy}{dx} = \frac{d\delta y}{dx}, \quad \delta y_2 = \frac{\delta d^2 y}{dx^2} = \frac{d^2 \delta y}{dx^2},$$

and so on. Hence, substituting and transposing,

$$\frac{d^n \delta y}{dx^n} - \frac{d\phi}{dy_{n-1}} \frac{d^{n-1} \delta y}{dx^{n-1}} - \frac{d\phi}{dy_{n-2}} \frac{d^{n-2} \delta y}{dx^{n-2}} - \&c. = 0 \dots (10).$$

Let us consider the real nature of this equation.

If a value of  $y$ , suppose  $y = \psi(x)$ , satisfy the given differential equation, that value substituted in the coefficients

$$\frac{d\phi}{dy_{n-1}}, \quad \frac{d\phi}{dy_{n-2}}, \quad \&c.$$

of the above equation will convert them into functions of  $x$ , and the equation itself will become a linear differential equation, the solution of which will determine  $\delta y$  as a function of  $x$ . If the differential equation (10) be really, as it is apparently, of the  $n^{\text{th}}$  degree,  $\delta y$  will have  $n$  arbitrary constants,  $\alpha_1, \dots \alpha_n$ , and will be of the form

$$\delta y = \alpha_1 P_1 + \alpha_2 P_2 \dots + \alpha_n P_n,$$

$P_1, P_2, \dots P_n$  being functions of  $x$ . Hence

$$y + \delta y = \psi(x) + \alpha_1 P_1 \dots + \alpha_n P_n.$$

We see thus that the given solution  $y = \psi(x)$  will be a *particular* case of this general integral involving  $n$  constants. It will therefore be a particular integral of the proposed.

If, owing to the constitution of its coefficients, the differential equation (10) be of the degree  $n - 1$ , we shall have

$$y + \delta y = \psi(x) + \alpha_1 P_1 \dots + \alpha_{n-1} P_{n-1},$$

and  $y = \psi(x)$  will then be a particular case of a solution involving  $n - 1$  arbitrary constants. It will therefore be a singular solution of the first order. Even so, if the differential equation (10) be of the degree  $n - 2$ ,  $y = \psi(x)$  will be a singular solution of the second order. And generally, if the differential equation be of the  $r^{\text{th}}$  degree,  $y = \psi(x)$  will be a singular solution of the order  $n - r$ .

Resuming the equation (10) it is evident that it cannot be of the degree  $n - 1$ , unless  $\frac{d\phi}{dy_{n-1}}$  be infinite. For, dividing by  $\frac{d\phi}{dy_{n-1}}$ , we have

$$\frac{1}{\frac{d\phi}{dy_{n-1}}} \cdot \frac{d^n \delta y}{dx^n} - \frac{d^{n-1} \delta y}{dx^{n-1}} - \&c. = 0,$$

in which the first term does not vanish unless  $\frac{d\phi}{dy_{n-1}}$  be infinite. This then is the necessary condition for a singular solution of the first order. For one of the second order we must have in like manner

$$\frac{d\phi}{dy_{n-1}} = \infty, \quad \frac{d\phi}{dy_{n-2}} = \infty;$$

and so on.

It follows hence that to find the singular solutions of a differential equation of the  $n^{\text{th}}$  order, we ought to differentiate the equation, regarding  $y$ ,  $\frac{dy}{dx}$ ,  $\frac{d^2 y}{dx^2}$ , &c. as varying through the variation of the arbitrary constants, to form in this way a linear differential equation for  $\delta y$ , to examine the conditions under which this equation reduces to the  $(n - 1)^{\text{th}}$ , or to a lower degree, and to examine whether the most general relation be-

tween  $x$  and  $y$  which satisfies such condition, satisfies also the given differential equation. If so it may be regarded as a singular solution.

Resuming the last Example, viz.

$$y - x \frac{dy}{dx} + \frac{1}{2} x^2 \frac{d^2y}{dx^2} - \left( \frac{d^2y}{dx^2} \right)^2 - \left( \frac{dy}{dx} - x \frac{d^2y}{dx^2} \right)^2 = 0,$$

and operating with  $\delta$  we have

$$\left\{ \frac{1}{2} x^2 - 2 \frac{d^2y}{dx^2} + 2x \left( \frac{dy}{dx} - x \frac{d^2y}{dx^2} \right) \right\} \frac{d^2\delta y}{dx^2} - \left\{ x + 2 \left( \frac{dy}{dx} - x \frac{d^2y}{dx^2} \right) \right\} \frac{d\delta y}{dx} + \delta y = 0,$$

which reduces to a linear differential equation of the first order for determining  $\delta y$ , provided that we have

$$\frac{1}{2} x^2 - 2 \frac{d^2y}{dx^2} + 2x \left( \frac{dy}{dx} - x \frac{d^2y}{dx^2} \right) = 0.$$

Eliminating  $\frac{d^2y}{dx^2}$  from the given equation by means of this there results

$$\left( \frac{dy}{dx} \right)^2 + \left( \frac{x^3}{2} + x \right) \frac{dy}{dx} - (1 + x^2) y - \frac{x^4}{16} = 0,$$

and we find on differentiating this that it does constitute a solution of the given equation. It is therefore a *singular* first integral of that equation. We see that it agrees with the result obtained under the same name in the previous Article, and the rest of the solution need not be repeated.

3. Upon Legendre's theory, and upon its results, the following observations may be made.

1st. We learn from it that there may exist different *general* forms of the solution of a differential equation of the  $n^{\text{th}}$  order, viz. the complete primitive involving  $n$  arbitrary

constants, and general forms of singular solutions containing fewer than  $n$  arbitrary constants. A solution  $y = \psi(x)$  of unknown origin being given, we construct a differential equation for determining  $\delta y$ , and, solving it, form the expression for  $y + \delta y$ , and from the number of infinitesimal arbitrary constants it contains, determine the nature of that general value of  $y$  of which the given value is a particular case. Now we are not to infer from this that the form of  $y + \delta y$  will be the same as the general value of  $y$  in question. But we may infer that it will be a form to which that general value is reducible. And the actual reduction will be effected by expressing the general solution (as is always possible) in a form permitting its expansion in ascending powers of the arbitrary constants, and in the expansion making these constants infinitesimal, and rejecting all powers of them above the first. In fact, if

$$y = f(x, a_1, a_2, \dots a_r)$$

be any *general* form of solution which, when we assign to  $a_1, a_2, \dots a_r$  particular values (e.g. make them vanish) reduces to

$$y = \psi(x),$$

then we shall have

$$y + \delta y = \psi(x) + \left(\frac{df}{da_1}\right) \delta a_1 + \left(\frac{df}{da_2}\right) \delta a_2 \dots + \left(\frac{df}{da_r}\right) \delta a_r,$$

the brackets denoting that after differentiation we make  $a_1, a_2, \dots a_r$  vanish.

This is that limiting form of the solution which Legendre's method enables us to construct by the solution of a linear differential equation; and the ground of the sufficiency of his method consists in this, that the infinitesimal quantities

$$\delta a_1, \delta a_2, \dots \delta a_r,$$

which are in fact the arbitrary constants of that solution, are equal in number to the arbitrary constants of the general unlimited solution, the nature of which is thus made known.

2ndly. Legendre's tests for differential equations of the higher orders are in kind and effect analogous to the tests

$$\frac{dp}{dy} = \infty, \quad \frac{d}{dx} \frac{1}{p} = \infty$$

for differential equations of the first order. They enable us to decide whether a solution possesses singularity, not whether it possesses the envelope species of singularity. The completion of Legendre's theory would consist in the discovery of those further tests dependent upon integration which correspond to the test of Euler and Cauchy for differential equations of the first order.

## CHAPTER XXIV.

## ADDITIONS TO CHAPTER XIV.

[Art. 1 was intended to follow Chap. XIV. Art. 2.]

1. As the condition of dependence of functions of two variables is of fundamental importance in connexion with the theory of ordinary differential equations, so the generalized condition of dependence of functions of any number of variables forms a fundamental part of the theory of partial differential equations. This is contained in the following proposition.

PROP. I. If  $u_1, u_2, \dots u_n$  are functions of  $x_1, x_2, \dots x_n$ , but are as such so related that some one of them is expressible as a function of the others, or more generally that there exists among them some identical equation of the form

$$F(u_1, u_2, \dots, u_n) = 0, \dots, \dots, \dots (1),$$

so that as functions of  $x_1, x_2, \dots, x_n$  they are not mutually independent, then, adopting the notation of determinants, the condition

$$\left[ \begin{array}{ccc} \frac{du_1}{dx_1}, & \frac{du_1}{dx_2}, & \dots \frac{du_1}{dx_n} \\ \frac{du_2}{dx_1}, & \frac{du_2}{dx_2}, & \dots \frac{du_2}{dx_n} \\ \dots & \dots & \dots \\ \frac{du_n}{dx_1}, & \frac{du_n}{dx_2}, & \dots \frac{du_n}{dx_n} \end{array} \right] = 0 \dots \dots \dots (2),$$

is identically satisfied. Conversely, if the above condition be identically satisfied, the functions  $u_1, u_2, \dots, u_n$  are not mutually independent in the sense above explained.

$$\left. \begin{aligned} \frac{du_1}{dx_1} dx_1 + \frac{du_1}{dx_2} dx_2 \dots + \frac{du_1}{dx_n} dx_n &= 0 \\ \frac{du_2}{dx_1} dx_1 + \frac{du_2}{dx_2} dx_2 \dots + \frac{du_2}{dx_n} dx_n &= 0 \\ \dots\dots\dots \\ \frac{du_{n-1}}{dx_1} dx_1 + \frac{du_{n-1}}{dx_2} dx_2 \dots + \frac{du_{n-1}}{dx_n} dx_n &= 0 \end{aligned} \right\} \dots\dots\dots (3),$$

then is

$$\frac{du_n}{dx_1} dx_1 + \frac{du_n}{dx_2} dx_2 \dots + \frac{du_n}{dx_n} dx_n = 0 \dots\dots\dots(4).$$

Thus the last  $n$  equations, linear with respect to

$$dx_1, dx_2, \dots dx_n,$$

are not independent, and therefore by the theory of linear equations the determinant of the system vanishes identically. Now this is expressed by the condition (2).

It remains to prove the converse, viz. that if the condition (2) be identically satisfied, the functions  $u_1, u_2, \dots u_n$  will not be mutually independent.

First, the  $n - 1$  functions  $u_1, u_2, \dots u_{n-1}$  are either mutually independent or not mutually independent.

If not, then the  $n$  functions  $u_1, u_2, \dots u_n$  are not mutually independent, and the Proposition to be proved is granted.

If  $u_1, u_2, \dots u_{n-1}$  are mutually independent as functions of  $x_1, x_2, \dots x_n$ , they may be made to take the place of  $n - 1$  of these quantities, e. g.  $x_1, x_2, \dots x_{n-1}$  in the expressing of  $u_n$ , i. e. we may, by means of the expressions for  $u_1, u_2, \dots u_{n-1}$ , eliminate from that of  $u_n$  the quantities  $x_1, x_2, \dots x_{n-1}$ , and so express  $u_n$  as a function of  $u_1, u_2, \dots u_{n-1}$  and  $x_n$ . Suppose this done, then the system (3), (4) will be converted into

$$du_1 = 0, \quad du_2 = 0, \quad \dots\dots du_{n-1} = 0,$$

$$\frac{du_n}{du_1} du_1 + \frac{du_n}{du_2} du_2 \dots + \frac{du_n}{du_{n-1}} du_{n-1} + \frac{du_n}{dx_n} dx_n = 0.$$

Now, the determinant (2) vanishing, the equations of the linear system (3), (4) are not independent; therefore those of the transformed system, as written above, are not independent; therefore the last equation of that system must be a consequence of the others which manifestly are independent. But from the form of that last equation we see that such cannot be the case unless we have

$$\frac{du_n}{dx_n} = 0,$$

which implies that  $u_n$  is a function of  $u_1, u_2, \dots u_{n-1}$  merely. Hence the functions  $u_1, u_2, \dots u_n$  are not independent, as was to be shewn.

The first member of the equation of condition (2) is commonly called the *functional determinant* of  $u_1, u_2, \dots u_n$  with respect to  $x_1, x_2, \dots x_n$ . The proposition may therefore be expressed as follows.

The condition of dependence or independence of any system of functions of as many variables is the vanishing or non-vanishing of the functional determinant of the system.

On account of the great importance of this proposition it is desirable to illustrate it by an example.

Ex. Are the functions

$$x + 2y + z, \quad x - 2y + 3z, \quad 2xy - xz + 4yz - 2z^2$$

mutually independent or not?

The equation of condition is

$$\begin{vmatrix} 1, & 2, & 1 \\ 1, & -2, & 3 \\ 2y - z, & 2x + 4z, & -x + 4y - 4z \end{vmatrix} = 0,$$

that is,

$$-4(-x + 4y - 4z) + 8(2y - z) - 2(2x + 4z) = 0,$$

which is identically satisfied. Hence the functions are dependent. In fact, representing them by  $u, v, w$ , we have

$$4w = u^2 - v^2.$$

[Art. 2 was intended to follow Chap. XIV. Art. 4.]

2. As it has been shewn that a primitive

$$u = \phi(v) \dots\dots\dots (1)$$

leads to a linear partial differential equation of the form

$$Pp + Qq = R \dots\dots\dots (2),$$

provided that  $u = a$ ,  $v = b$ , are integrals of the system of ordinary differential equations

$$\frac{dx}{P} = \frac{dy}{Q} = \frac{dz}{R} \dots\dots\dots (3),$$

it is evident that we shall obtain a solution of the partial differential equation (2) by constructing the system of ordinary differential equations (3), deducing their general integrals

$$u = a, \quad v = b,$$

and then constructing from these the primitive (1).

But the question arises, Will this be the most general solution of the partial differential equation given?

That it will be so, may be shewn by means of the general proposition. See Art. 1.

For let  $w = 0$  represent any solution whatever of the given partial differential equation. Differentiating this with respect to  $x$  and  $y$ , we have

$$\frac{dw}{dx} + \frac{dw}{dz} p = 0, \quad \frac{dw}{dy} + \frac{dw}{dz} q = 0,$$

substituting the values of  $p$  and  $q$  formed from this in the given equation, we have

$$P \frac{dw}{dx} + Q \frac{dw}{dy} + R \frac{dw}{dz} = 0,$$

which must be identically satisfied.

In like manner,  $u = a$ ,  $v = b$  being solutions of the same equation, we find

$$P \frac{du}{dx} + Q \frac{du}{dy} + R \frac{du}{dz} = 0,$$

$$P \frac{dv}{dx} + Q \frac{dv}{dy} + R \frac{dv}{dz} = 0,$$

which must be identically satisfied.

Eliminating  $P, Q, R$  from these three equations, it results that *the functional determinant of  $w, u, v$ , with respect to  $x, y, z$ , will identically vanish*. Hence  $w$  is a function of  $u$  and  $v$ , and the equation  $w = 0$  is a particular case of

$$F(u, v) = 0,$$

which is thus shewn to be the *general* integral of the given equation.

We are thus led to the following general Rule.

**RULE.** *To integrate the equation  $Pp + Qq = R$  we must form the system of ordinary differential equations*

$$\frac{dx}{P} = \frac{dy}{Q} = \frac{dz}{R},$$

*deduce their general integrals in the form*

$$u = a, \quad v = b,$$

*and construct the equation*

$$F(u, v) = 0.$$

This will be the general solution sought.

[Art. 3 was intended to follow Chap. XIV. Art. 5.]

3. The above theory may be extended to linear partial differential equations of the first order, without regard to the number of the variables.

First, the theory of the genesis of such equations is expressed in the following proposition.

**PROP.** A primitive equation of the form

$$F(u_1, u_2, \dots u_n) = 0 \dots\dots\dots (1),$$

in which  $u_1, u_2, \dots u_n$  are any given functions of the variables  $z$ , dependent, and  $x_1, x_2, \dots x_n$  independent, will satisfy the linear partial differential equation obtained by eliminating  $dz, dx_1, dx_2, \dots dx_n$  from

$$du_1 = 0, \quad du_2 = 0, \dots\dots du_n = 0,$$

expressed as total differential equations with respect to the primitive variables, and the equation

$$dz - p_1 dx_1 - p_2 dx_2 \dots - p_n dx_n = 0.$$

Of this important proposition I propose to give two distinct proofs.

1st proof. Forming the total differential of the given equation we have, on representing its first member by  $F$ ,

$$\frac{dF}{du_1} du_1 + \frac{dF}{du_2} du_2 \dots + \frac{dF}{du_n} du_n = 0.$$

Now this cannot be true for all forms of the function unless we have the separate conditions

$$du_1 = 0, \quad du_2 = 0, \dots du_n = 0.$$

Strictly to prove this, suppose  $F_1, F_2, \dots F_n$  to be any  $n$  distinct and independent functions of  $u_1, u_2, \dots u_n$ , and as such, distinct and independent forms of  $F$ . Then the above equation gives

$$\frac{dF_1}{du_1} du_1 + \frac{dF_1}{du_2} du_2 \dots + \frac{dF_1}{du_n} du_n = 0,$$

$$\frac{dF_2}{du_1} du_1 + \frac{dF_2}{du_2} du_2 \dots + \frac{dF_2}{du_n} du_n = 0,$$

.....

$$\frac{dF_n}{du_1} du_1 + \frac{dF_n}{du_2} du_2 \dots + \frac{dF_n}{du_n} du_n = 0.$$

Now  $F_1, F_2, \dots F_n$  being independent, their functional determinant with respect to  $u_1, u_2, \dots u_n$ , does not vanish. This again is the condition necessary and sufficient that the above system of linear equations may be independent; and this lastly being the case, their only possible solution will be

$$du_1 = 0, \quad du_2 = 0, \dots du_n = 0,$$

as was to be shewn.

which is the determinant form of the result affirmed in the proposition.

The second of the above forms of demonstration seems to be preferable to the first, in that it rests only upon the consideration of the one general form of the function  $F$ . I have, however, given the two proofs, chiefly in order to illustrate an important remark, viz. that, in nearly all general researches connected with partial differential equations of the first order, two modes of procedure, the one involving the use of differentials, the other that of differential coefficients, may be employed, and that between the forms to which these respective modes give rise, a certain law of reciprocity will be found to exist.

The theory of the solution of the partial differential equation

$$X_1 p_1 + X_2 p_2 \dots + X_n p_n = R$$

follows immediately from that of its genesis. If we represent by

$$u_1 = a_1, \quad u_2 = a_2, \dots u_n = a_n,$$

the integrals of the system of ordinary differential equations (2) a solution of the given partial differential equation will be represented by (1). That this will be also the most general solution may be shewn by the argument of Art. 1. For if  $w = 0$  represent any solution, then since

$$\frac{dw}{dx_1} + p_1 \frac{dw}{dz} = 0, \dots \frac{dw}{dx_n} + p_n \frac{dw}{dz} = 0,$$

we find

$$X_1 \frac{dw}{dx_1} + X_2 \frac{dw}{dx_2} \dots + X_n \frac{dw}{dx_n} + R \frac{dw}{dz} = 0,$$

from which, in combination with the corresponding equations,

$$X_1 \frac{du_1}{dx_1} + X_2 \frac{du_1}{dx_2} \dots + X_n \frac{du_1}{dx_n} + R \frac{du_1}{dz} = 0,$$

.....

$$X_1 \frac{du_n}{dx_1} + X_2 \frac{du_n}{dx_2} \dots + X_n \frac{du_n}{dx_n} + R \frac{du_n}{dz} = 0,$$

eliminating  $X_1, X_2, \dots, X_n, R$  we obtain a result which expresses that the functional determinant of  $w, u_1, \dots, u_n$  with respect to the original variables is virtually 0. Whence  $w$  is a function of  $u_1, u_2, \dots, u_n$ , and the proposed solution is included in the one to which the above method of solution leads.

That method may therefore be stated in the following Rule.

RULE. *To integrate the linear partial differential equation*

$$X_1 \frac{dz}{dx_1} + X_2 \frac{dz}{dx_2} \dots + X_n \frac{dz}{dx_n} = R$$

*form the system of ordinary differential equations*

$$\frac{dx_1}{X_1} = \frac{dx_2}{X_2} \dots = \frac{dx_n}{X_n} = \frac{dz}{R},$$

*and deduce their general integrals*

$$u_1 = a_1, \quad u_2 = a_2, \quad \dots \quad u_n = a_n,$$

*then*

$$F(u_1, u_2, \dots, u_n) = 0$$

*will be the general integral sought.*

[The *general observations* were intended to follow Chap. XIV. Art. 6.]

#### *General observations.*

4. The relation which exists between a proposed linear partial differential equation and its auxiliary system of ordinary differential equations should be carefully studied. While it is proper to say as above that the general integral of the one requires the knowledge of all the integrals of the other, it is also proper to describe that general integral simply as the most general form under which an integral of the auxiliary system can appear. If

$$u_1 = a_1, \quad u_2 = a_2, \quad \dots \quad u_n = a_n$$

are integrals of that system, then

$$F(u_1, u_2, \dots, u_n) = A$$

is the one general form of an integral of that system, and due regard being had to the arbitrariness of  $F$ , this is equivalent to

$$F(u_1, u_2, \dots u_n) = 0.$$

5. The form which the auxiliary system assumes when the given partial differential equation is deficient in any of its terms should be noticed.

If  $X_1 = 0$ , the auxiliary equation

$$\frac{dx_1}{X_1} = \frac{dx_2}{X_2}$$

becomes, on clearing of fractions,

$$dx_1 = 0.$$

And thus, if  $X_1, X_2, \dots X_r$  vanish, the given equation being

$$X_1 \frac{dz}{dx_1} \dots + X_{r+1} \frac{dz}{dx_{r+1}} \dots + X_n \frac{dz}{dx_n} = X,$$

the auxiliary system will be

$$\begin{aligned} dx_1 = 0, \quad dx_2 = 0, \dots dx_r = 0, \\ \frac{dx_{r+1}}{X_{r+1}} = \frac{dx_{r+2}}{X_{r+2}} \dots = \frac{dx_n}{X_n} = \frac{dz}{X}, \end{aligned}$$

and the integrals of this system being of the form

$$x_1 = a_1, \quad x_2 = a_2, \dots x_r = a_r,$$

$$u_{r+1} = a_{r+1}, \dots u_n = a_n,$$

the general solution of the given equation will be

$$F(x_1, \dots x_r, u_{r+1}, \dots u_n) = 0.$$

This conclusion would follow also from the principle laid down in Chap. XIV. Art. 2.

Linear partial differential equations in which the absolute term is wanting, and which are therefore of the form

$$X_1 \frac{dz}{dx_1} + X_2 \frac{dz}{dx_2} \dots + X_n \frac{dz}{dx_n} = 0,$$

may be termed homogeneous. As in this case one of the auxiliary equations is

$$dz = 0,$$

the general integral will be

$$F(u_1, u_2, \dots u_{n-1}, z) = 0,$$

$u_1, u_2, \dots u_{n-1}$  being found by the integration of the remaining auxiliary equations

$$\frac{dx_1}{X_1} = \frac{dx_2}{X_2} \dots = \frac{dx_n}{X_n}.$$

When  $X_1, X_2, \dots X_n$  do not contain  $z$ , the solution is best exhibited in the form

$$z = \phi(u_1, u_2, \dots u_{n-1}).$$

6. Every linear partial differential equation can be converted into a homogeneous one containing one additional variable. For it is shewn in Art. 3, that if  $u = 0$  be any integral of

$$X_1 \frac{dz}{dx_1} + X_2 \frac{dz}{dx_2} \dots + X_n \frac{dz}{dx_n} = X,$$

then is

$$X_1 \frac{du}{dx_1} + X_2 \frac{du}{dx_2} \dots + X_n \frac{du}{dx_n} + X \frac{du}{dz} = 0,$$

a homogeneous equation with a new variable.

From the general integral of this equation, that of the former one may be deduced by making  $u = 0$ .

7. The solution of partial differential equations is sometimes facilitated by introducing a new system of independent variables. The actual transformation is greatly facilitated by the following symbolical theorem.

THEOREM. If the partial differential equation

$$X_1 \frac{dz}{dx_1} + X_2 \frac{dz}{dx_2} \dots + X_n \frac{dz}{dx_n} = X$$

be expressed symbolically in the form

$$\Delta z = X,$$

in which

$$\Delta = X_1 \frac{d}{dx_1} + X_2 \frac{d}{dx_2} \dots + X_n \frac{d}{dx_n},$$

then, if  $y_1, y_2, \dots, y_n$  be a new system of independent variables given in expression as functions of the old ones, the transformed equation will be

$$(\Delta y_1) \frac{dz}{dy_1} + (\Delta y_2) \frac{dz}{dy_2} \dots + (\Delta y_n) \frac{dz}{dy_n} = X.$$

For, regarding  $z$  as a function of  $y_1, y_2, \dots, y_n$ , we have

$$\begin{aligned} \frac{dz}{dx_1} &= \frac{dz}{dy_1} \frac{dy_1}{dx_1} + \frac{dz}{dy_2} \frac{dy_2}{dx_1} \dots + \frac{dz}{dy_n} \frac{dy_n}{dx_1}, \\ &\dots\dots\dots \\ \frac{dz}{dx_n} &= \frac{dz}{dy_1} \frac{dy_1}{dx_n} + \frac{dz}{dy_2} \frac{dy_2}{dx_n} \dots + \frac{dz}{dy_n} \frac{dy_n}{dx_n}; \end{aligned}$$

whence, substituting in the given equation we find, as the total coefficient of  $\frac{dz}{dy_1}$ , the expression

$$X_1 \frac{dy_1}{dx_1} + X_2 \frac{dy_1}{dx_2} \dots + X_n \frac{dy_1}{dx_n},$$

or symbolically,  $\Delta y_1$ ; and so on for the other coefficients. The result then is

$$(\Delta y_1) \frac{dz}{dy_1} + (\Delta y_2) \frac{dz}{dy_2} \dots + (\Delta y_n) \frac{dz}{dy_n} = X.$$

It remains only after calculation of  $\Delta y_1, \Delta y_2, \dots, \Delta y_n$ , as functions of  $x_1, x_2, \dots, x_n$ , to express these functions and  $X$  in terms of  $y_1, y_2, \dots, y_n$ .

[It appears from the manuscript that an example was to have been supplied here.]

[The next Article may be considered supplementary to Chap. XIV. Art. 10.]

*Singular Solutions of partial Differential Equations.*

8. Legendre's theory developed in Chap. XXIII. for ordinary, may be applied also without essential change to partial, differential equations. Regarding the independent variable  $z$  as receiving an infinitesimal change  $\delta z$  through infinitesimal change, not in the values of the independent variables

$$x_1, x_2, \dots x_n,$$

but in the values of the arbitrary constants of the complete or in the forms of the arbitrary functions of the general integral, and performing upon the given equation the operation denoted by  $\delta$ , we shall obtain a *linear* partial differential equation for determining the general value of  $\delta z$  corresponding to any particular given value of  $z$ . If that linear equation be of a lower order than the differential equation given, then the equation expressing the value of  $z + \delta z$  will be a limiting form of a solution less complete or less general than the complete or general solution of the differential equation given, and the given solution, formed by making the infinitesimal constants in the limiting form actually 0, will be singular.

Conversely, to deduce singular solutions without the knowledge of the complete or the general integral, we ought to construct the equations of condition for the reduction of the equation determining  $\delta z$  to a lower order than the equation given, and the most general solution of the differential equations of condition so formed, will be the most general expression for the singular solutions of the differential equation given.

Ex.  $(px - qy)^2 q + 4mx^3 (z - xp) = 0,$

in which

$$p = \frac{dz}{dx}, \quad q = \frac{dz}{dy}.$$

Representing the first member of the equation by  $F$ , we have, on operating by  $\delta$ ,

$$\frac{dF}{dp} \frac{d\delta z}{dx} + \frac{dF}{dq} \frac{d\delta z}{dy} + \frac{dF}{dz} \delta z = 0,$$

and the conditions

$$\frac{dF}{dp} = 0, \quad \frac{dF}{dq} = 0,$$

necessary to reduce the equation for  $\delta z$  to a lower order give

$$\begin{aligned} (px - qy) q - 2mx^3 &= 0, \\ (px - qy) (px - 3qy) &= 0. \end{aligned}$$

From these we find

$$p = 3m^{\frac{1}{2}}x^{\frac{1}{2}}y^{\frac{1}{2}}, \quad q = m^{\frac{1}{2}}x^{\frac{3}{2}}y^{-\frac{1}{2}},$$

definite and simultaneous values of  $p$  and  $q$ , which being substituted in the given equation lead to

$$z = 2m^{\frac{1}{2}}x^{\frac{3}{2}}y^{\frac{1}{2}},$$

and this, as it gives the same values of  $p$  and  $q$  as those obtained before, will necessarily satisfy the given equation. It is therefore a solution, and from the nature of the analysis, a singular one.

Legendre shews that this singular solution is also deducible from the general integral of the given partial differential equation. That integral is the result of the elimination of  $a$  from the two equations

$$\begin{aligned} \{\phi(a)\}^2 - 2ax\phi(a) + az - mxy &= 0, \\ \{\phi(a) - ax\} \phi'(a) - 2x\phi(a) + z &= 0. \end{aligned}$$

To deduce the singular solution he supposes  $\phi(a)$  to be *not* simply a function of  $a$ , but a function of  $a$  and of one or both of the independent variables. He expresses the varia-

tion of  $\phi(a)$  derived from this new source by  $\delta$ , and operating on the first equation with  $\delta$ , finds

$$\{2\phi(a) - 2ax\} \delta\phi(a) = 0;$$

therefore  $\phi(a) = ax$ .

Substituting this in the equations of the general integral, and eliminating  $a$ , we find

$$z = 2m^{\frac{1}{2}}x^{\frac{3}{2}}y^{\frac{1}{2}}$$

as before.

Legendre states his theory of the derivation of the singular solutions of partial differential equations from the equations themselves with great brevity, but still as a *general* theory. And there is nothing in the statement that carries with it any apparent restriction upon either the order or the degree of the equations given. Until however we are in possession of a perfect theory of the *genesis* of partial differential equations we shall not be entitled to say that Legendre's theory of their singular solutions is a perfect one; for until then we cannot even define, in a perfectly general way, the nature of the operation denoted by  $\delta$ .

[The next three Chapters all relate to the subject of partial differential equations of the first order. The manuscripts do not appear to have received their final revision from Professor Boole. It is certain that he intended the contents of Chapter xxv. to form a part of the new edition; and it is highly probable, although not certain, that the contents of Chapter xxvi. and Chapter xxvii. were also to be included.

The three Chapters are mainly derived from two memoirs by Professor Boole, published in the *Philosophical Transactions*.

The first memoir is entitled *On Simultaneous Differential Equations of the First Order in which the Number of the Variables exceeds by more than one the Number of the Equations*: it occupies pages 437...454 of the *Philosophical Transactions* for 1862.

The second memoir is entitled *On the Differential Equations of Dynamics. A sequel to a Paper on Simultaneous Differential Equations*: it occupies pages 485...501 of the *Philosophical Transactions* for 1863.

The first memoir was finished before Professor Boole had seen Jacobi's researches, which are cited at the beginning of Chapter xxvi; these researches indeed could only just have been published. In his second memoir Professor Boole describes Jacobi's methods, refers to his own already published, and points out the nature of the connexion between them.]

## CHAPTER XXV.

## ON SYSTEMS OF SIMULTANEOUS LINEAR PARTIAL DIFFERENTIAL EQUATIONS OF THE FIRST ORDER, AND ON ASSOCIATED SYSTEMS OF ORDINARY DIFFERENTIAL EQUATIONS.

1. THE term *simultaneous* is here applied to a system of partial differential equations, to signify that in that system there is but one dependent variable, the general expression of which, as a function of the independent variables satisfying all the equations at once, is the object of search. All linear partial differential equations of the first order being reducible to the homogeneous form, we shall presuppose this reduction here. Under this form indeed the problem actually presents itself in Geometry, in the theory of partial differential equations of the second order, and in Theoretical Dynamics.

We are sometimes led, in connexion with the same class of inquiries, to systems of ordinary differential equations marked by the peculiarity that the number of the variables exceeds by more than one the number of the equations. Such systems are intimately connected with the former—stand to them indeed in a similar relation to that which the Lagrangean auxiliary system bears to the *single* partial differential equation from which it arises. The theory which explains this connexion, and grounds upon it the method of solution of both systems will form the subject of the present Chapter.

*Connexion of the Systems.*

2. PROP. I. The solution of a system of simultaneous linear partial differential equations of the first order may be

a single partial differential equation which, on account of the arbitrariness of  $\lambda_1, \lambda_2, \dots, \lambda_n$ , is equivalent to the system from which it was formed.

Of this equation the Lagrangean auxiliary system will be

$$\begin{aligned} \frac{dx_1}{\lambda_1} &= \frac{dx_2}{\lambda_2} \dots\dots = \frac{dx_n}{\lambda_n} \\ &= \frac{dx_{n+1}}{\lambda_1 A_{11} + \lambda_2 A_{21} \dots\dots + \lambda_n A_{n1}} \\ &= \dots\dots \\ &= \frac{dx_{n+r}}{\lambda_1 A_{1r} + \lambda_2 A_{2r} \dots\dots + \lambda_n A_{nr}} \dots\dots\dots (3), \end{aligned}$$

whence, eliminating  $\lambda_1, \lambda_2, \dots, \lambda_n$ , we have the system of ordinary differential equations

$$\left. \begin{aligned} dx_{n+1} - A_{11}dx_1 - A_{21}dx_2 \dots - A_{n1}dx_n &= 0 \\ dx_{n+2} - A_{12}dx_1 - A_{22}dx_2 \dots - A_{n2}dx_n &= 0 \\ \dots\dots\dots \\ dx_{n+r} - A_{1r}dx_1 - A_{2r}dx_2 \dots - A_{nr}dx_n &= 0 \end{aligned} \right\} \dots\dots\dots (4),$$

These equations being included in the previous system (3), any integrals

$$u = a, \quad v = b, \quad w = c, \quad \&c.$$

of them will be integrals of it. Therefore  $u, v, w, \dots$  will be values of  $P$  satisfying the partial differential equation (2). For they will be the only values which can satisfy it independently of  $\lambda_1, \lambda_2, \dots, \lambda_n$ . Hence they will satisfy the equivalent system (1), and the general integral of that system will be

$$F(u, v, w, \dots) = 0 \dots\dots\dots (5),$$

the form of  $F$  being arbitrary.

Thus the relation of the system (4) to the system (1) is the same as the relation of the auxiliary system of a single linear

*of differentials  $dx_1, dx_2, \dots$  equal to that of the given equations, and then equate to 0 the coefficients of the remaining differentials.*

4. Lastly, the formal connexion of the two systems should be noticed. The partial differential equations being given in the reduced form (1), the ordinary system may be constructed as follows: For any differential coefficient, as  $\frac{dP}{dx_{n+1}}$ , in any column after the first, write the corresponding differential  $dx_{n+1}$ , subtract from this the sum of  $dx_1, dx_2, \dots, dx_n$ , multiplied respectively by the descending coefficients of that column, and equate the result to 0. The system of equations thus successively formed will be the auxiliary system sought.

The transition from the ordinary to the partial system may be effected by the same rule, substituting only differentials for differential coefficients.

[It appears from the manuscript that an example was to have been supplied here.]

Up to this point the theory of systems of partial differential equations is in analogy with that of single equations. But here a difference arises. We do not know beforehand what number of integrals a system of ordinary differential equations, in which the number of variables exceeds by more than one the number of the equations, admits.

The theory which removes this difficulty will be developed in the following sections. It will be shewn that a system of linear partial differential equations which admits of solution by the assigning to the dependent variable a value which satisfies all the equations in common, must either itself satisfy a certain condition, or be capable of being developed into a new but equivalent system which will satisfy that condition. It will be shewn that when that condition is satisfied, the auxiliary system of ordinary, is capable of expression as a system of *exact* differential equations determining the integrals sought.

It will be found convenient to express by a single symbol the aggregate of the operations to which the dependent variable is subject in the expression of a partial differential equation. Thus the equation

$$\frac{dz}{dt} + x \frac{dz}{dx} + y \frac{dz}{dy} = 0$$

may be expressed in the form

$$\Delta z = 0$$

if we assume

$$\Delta = \frac{d}{dt} + x \frac{d}{dx} + y \frac{d}{dy}.$$

Under this convention the following proposition is to be understood.

5. PROP. II. If  $\Delta P = 0$ ,  $\Delta' P = 0$  represent any two homogeneous linear partial differential equations of the first order, then will

$$(\Delta\Delta' - \Delta'\Delta) P = 0$$

also be a homogeneous linear partial differential equation of the first order, and it will be satisfied by all the common integrals of the equations from which it is derived.

First, the equation will be linear. For, let  $x, y$  represent any two variables whatever, or the same variable repeated, out of the set  $x_1 \dots x_n$ , and let  $A, B$  represent any functions of the variables  $x_1 \dots x_n$ . Then  $\Delta$  may be represented by a series of terms of the form  $A \frac{d}{dx}$ , and  $\Delta'$  by a series of terms of the form  $B \frac{d}{dy}$ . Hence  $(\Delta\Delta' - \Delta'\Delta) P$  can be expressed by a series of terms of the form

$$A \frac{d}{dx} \left( B \frac{dP}{dy} \right) - B \frac{d}{dy} \left( A \frac{dP}{dx} \right),$$

which, on effecting the differentiations, becomes

$$A \frac{dB}{dx} \frac{dP}{dy} - B \frac{dA}{dy} \frac{dP}{dx},$$

the terms containing the second differential coefficients of  $P$  mutually destroying each other. Hence the equation

$$(\Delta\Delta' - \Delta'\Delta)P = 0$$

will be a homogeneous linear partial differential equation of the first order.

The constitution of the coefficients of this equation is easily determined. For suppose the given equations to be

$$A_1 \frac{dP}{dx_1} + A_2 \frac{dP}{dx_2} \dots\dots + A_n \frac{dP}{dx_n} = 0,$$

$$B_1 \frac{dP}{dx_1} + B_2 \frac{dP}{dx_2} \dots\dots + B_n \frac{dP}{dx_n} = 0,$$

so that

$$\Delta = A_1 \frac{d}{dx_1} \dots\dots + A_n \frac{d}{dx_n}, \quad \Delta' = B_1 \frac{d}{dx_1} \dots\dots + B_n \frac{d}{dx_n},$$

then the equation

$$(\Delta\Delta' - \Delta'\Delta)P = 0$$

may be written in the form

$$\Delta \left( B_1 \frac{dP}{dx_1} + B_2 \frac{dP}{dx_2} \dots\dots + B_n \frac{dP}{dx_n} \right) - \Delta' \left( A_1 \frac{dP}{dx_1} + A_2 \frac{dP}{dx_2} \dots\dots + A_n \frac{dP}{dx_n} \right),$$

and, since terms involving second differential coefficients of  $P$  will disappear, this becomes

$$\begin{aligned} (\Delta B_1 - \Delta' A_1) \frac{dP}{dx_1} + (\Delta B_2 - \Delta' A_2) \frac{dP}{dx_2} \dots\dots \\ + (\Delta B_n - \Delta' A_n) \frac{dP}{dx_n} = 0. \end{aligned}$$

We see from this that the *form of the result is the same as if the  $\Delta$  or  $\Delta'$  from either equation operated only on the coefficients in the other equation.*

Secondly, the above equation will be satisfied by all the common integrals of the equations from which it is derived.

For, let  $\phi = c$  be a common integral of

$$\Delta P = 0 \quad \text{and} \quad \Delta' P = 0,$$

then

$$\Delta \phi = 0, \quad \Delta' \phi = 0.$$

Performing on these the respective operations  $\Delta'$  and  $\Delta$ , operations which involve only differentiation together with algebraic processes, we have

$$\Delta' \Delta \phi = 0, \quad \Delta \Delta' \phi = 0,$$

whence, by subtraction,

$$\Delta \Delta' \phi - \Delta' \Delta \phi = 0,$$

or

$$(\Delta \Delta' - \Delta' \Delta) \phi = 0,$$

from which it appears that  $\phi$  is also an integral of the equation

$$(\Delta \Delta' - \Delta' \Delta) P = 0,$$

as was to be shewn.

6. PROP. III. If by the above processes of reduction and derivation we convert a system of partial differential equations into a new system, such that if expressed in the form

$$\Delta_1 P = 0, \quad \Delta_2 P = 0, \quad \dots \quad \Delta_m P = 0,$$

the condition

$$(\Delta_i \Delta_j - \Delta_j \Delta_i) P = 0$$

shall for each pair of equations be identically satisfied, then the system of ordinary differential equations corresponding to this new system will admit of reduction to the form of *exact* differential equations, the integration of which will enable us to construct the general value of  $P$  satisfying the system given.

1st. Suppose the given system of  $n$  equations reduced to the form (1), marked by the peculiarity that  $n$  of the differential coefficients appear only in successive equations and with the coefficient unity. Then taking any two of those equations (we select the first two), we have

$$\Delta_1 = \frac{d}{dx_1} + A_{11} \frac{d}{dx_{n+1}} \dots\dots + A_{1r} \frac{d}{dx_{n+r}},$$

$$\Delta_2 = \frac{d}{dx_2} + A_{21} \frac{d}{dx_{n+1}} \dots\dots + A_{2r} \frac{d}{dx_{n+r}},$$

from the forms of which we see that the derived equation

$$(\Delta_1 \Delta_2 - \Delta_2 \Delta_1) P = 0$$

cannot contain either

$$\frac{dP}{dx_1} \text{ or } \frac{dP}{dx_2}.$$

It can only, as appears from Art. 5, contain the differential coefficients

$$\frac{dP}{dx_{n+1}}, \dots\dots \frac{dP}{dx_{n+r}},$$

and must be of the form

$$B_1 \frac{dP}{dx_{n+1}} + B_2 \frac{dP}{dx_{n+2}} \dots\dots + B_r \frac{dP}{dx_{n+r}} = 0.$$

It cannot therefore be an *algebraic* consequence of any of the equations of the system (1) from which it was derived. It is, unless by the vanishing of  $B_1, \dots B_r$  it present itself as an identity, a *new* equation algebraically independent. Combining this with the former ones, we have a system of  $n+1$  equations admitting of the same reduction as to form followed by the same subsequent process of derivation. And the result of each of these completed steps is to convert the system into one containing one equation more than before; but containing in each of its equations one term fewer than before. The process must then end either in the genesis of a system of partial differential equations such that the further

application of the process of derivation of Prop. II. shall only lead to identities, or in the emerging of the system

$$\frac{dP}{dx_1} = 0, \quad \frac{dP}{dx_2} = 0, \dots \frac{dP}{dx_{n+r}} = 0.$$

The latter supposition would imply that  $P$  is a constant. The consequences of the former we proceed to examine.

The final system of linear partial differential equations will be of the same type (1) as the original system, but will differ from that system in that  $n$  will be increased, and  $r$  diminished by the same amount. We shall therefore simply state the form (1), only under the condition

$$(\Delta_i \Delta_j - \Delta_j \Delta_i) P = 0,$$

and with the altered values of  $n$  and  $r$ .

First, then, the common integrals of the new system will be the same as those of the original system. This is evident from Prop. II.

Secondly. If we write

$$m = n + r,$$

the first equation of the system (1) will be

$$\frac{dP}{dx_1} + A_{11} \frac{dP}{dx_{n+1}} + A_{12} \frac{dP}{dx_{n+2}} \dots + A_{1r} \frac{dP}{dx_m} = 0,$$

and the auxiliary Lagrangean system of this will have  $m - 1$  independent integrals

$$u_1 = c_1, \quad u_2 = c_2, \dots u_{m-1} = c_{m-1},$$

among which the  $n - 1$  known integrals (Chap. XXIV. Art. 5)

$$x_2 = c_2, \quad x_3 = c_3, \quad x_n = c_n$$

are included. And the general value of  $P$  satisfying the above first equation will be

$$P = F(u_1, u_2, \dots, u_{m-1}).$$

The assumption  $P = x_1$  would not satisfy the said equation, for it would lead, on substitution, to  $1 = 0$ . Hence we infer that while the functions  $u_1, u_2, \dots, u_{m-1}$  are independent with respect to each other, they are also independent with respect to  $x_1$ , so that the  $m$  functions  $u_1, u_2, \dots, u_{m-1}, x_1$ , are mutually independent in the sense explained in Chap. XXIV.

Let us now transform the equations of the system (1) after the first by introducing  $u_1, u_2, \dots, u_{m-1}, x_1$  as independent variables. Those equations being

$$\Delta_2 P = 0, \dots, \Delta_n P = 0,$$

the result of the transformation will be (Chap. XXIV. Art. 7)

$$(\Delta_2 u_1) \frac{dP}{du_1} + (\Delta_2 u_2) \frac{dP}{du_2} \dots + (\Delta_2 u_{m-1}) \frac{dP}{du_{m-1}} + (\Delta_2 x_1) \frac{dP}{dx_1} = 0,$$

.....

$$(\Delta_n u_1) \frac{dP}{du_1} + (\Delta_n u_2) \frac{dP}{du_2} \dots + (\Delta_n u_{m-1}) \frac{dP}{du_{m-1}} + (\Delta_n x_1) \frac{dP}{dx_1} = 0.$$

But  $P = x_1$  being an integral of each of the equations of the system (1) except the first, as appears from their forms, we have

$$\Delta_2 x_1 = 0, \dots, \Delta_n x_1 = 0,$$

thus the last terms in the transformed system vanish. Further, the coefficients of the remaining terms reduce to functions of  $u_1, u_2, \dots, u_{m-1}$  merely. For, considering the coefficient  $\Delta_2 u_1$ , we have

$$(\Delta_1 \Delta_2 - \Delta_2 \Delta_1) u_1 = 0,$$

which, since  $\Delta_1 u_1 = 0$  reduces to

$$\Delta_1 \Delta_2 u_1 = 0.$$

Hence  $\Delta_2 u_1$  must be a solution of  $\Delta_1 P = 0$ , and therefore a function of  $u_1, u_2, \dots, u_{m-1}$ . And so for the others. It results therefore that the transformed system is

$$(\Delta_2 u_1) \frac{dP}{du_1} + (\Delta_2 u_2) \frac{dP}{du_2} \dots + (\Delta_2 u_{m-1}) \frac{dP}{du_{m-1}} = 0,$$

.....

$$(\Delta_n u_1) \frac{dP}{du_1} + (\Delta_n u_2) \frac{dP}{du_2} \dots + (\Delta_n u_{m-1}) \frac{dP}{du_{m-1}} = 0,$$

$u_1, u_2, \dots, u_{m-1}$  being the *actual* independent variables of the system.

But the transformation having involved no loss of generality, for a new system of  $m$  independent variables was simply substituted for an old one, the condition

$$(\Delta_i \Delta_j - \Delta_j \Delta_i) P = 0,$$

satisfied before, will continue to be satisfied in the new system represented symbolically in the form

$$\Delta_2 P = 0, \Delta_3 P = 0, \dots, \Delta_n P = 0.$$

Any common integrals of this system will also be common integrals of the previous system. For as functions of

$$u_1, u_2, \dots, u_{m-1}$$

they will satisfy the first equation of that system, and they will satisfy the other equations, because the present system is but a transformation of those. The converse is equally manifest.

Thus a system of  $n$  partial differential equations containing  $m$  independent variables and satisfying a certain condi-

tion, has in virtue of that condition been converted into a system of  $n - 1$  equations between  $m - 1$  independent variables, and satisfying the same condition. This then is convertible into a similarly constituted system of  $n - 2$  equations containing  $m - 2$  independent variables, and so on till we arrive at a final single partial differential equation containing  $m - n + 1$  independent variables. This equation has  $m - n$ , that is,  $r$  integrals, and these are the common integrals of the system (1).

But the system of *ordinary* differential equations corresponding to (1) is in number  $r$ , and is satisfied by all the common integrals of that system. Hence these differential equations must admit of reduction to the exact form.

7. We may deduce from the above investigation the following Rule.

To integrate a system of simultaneous linear partial differential equations of the first order.

**RULE.** Reduce the equations to the homogeneous form (1), express the result symbolically by

$$\Delta_1 P = 0, \quad \Delta_2 P = 0, \quad \dots \quad \Delta_n P = 0,$$

and examine whether the condition

$$(\Delta_i \Delta_j - \Delta_j \Delta_i) P = 0$$

is identically satisfied for every pair of equations of the system. If it be so, the equations of the auxiliary system, Prop. I., will be reducible to the exact form, and their integrals being

$$u = a, \quad v = b, \quad w = c, \quad \dots$$

the complete value of  $P$  will be  $F(u, v, w, \dots)$ , the form of  $F$  being arbitrary.

If the condition be not identically satisfied, its application will give rise to one or more new partial differential equations. Combine any one of these with the previous reduced

system, and again reduce in the same way. With the new reduced system proceed as before, and continue this method of reduction and derivation until either a system of partial differential equations arises between every two of which the above condition is identically satisfied, or, which is the only possible alternative, the system

$$\frac{dP}{dx_1} = 0, \quad \frac{dP}{dx_2} = 0, \dots$$

appears. In the former case the system of ordinary equations corresponding to the final system of partial differential equations will admit of reduction to the exact form, and the general value of  $P$  will emerge from their integrals as above. In the latter case the given system can only be satisfied by supposing  $P$  a constant.

Ultimately then the determination of  $P$  depends on the solution of a system of ordinary differential equations reducible to the exact form. This does not mean that each equation of the system is reducible to the exact form, but that the equations may be combined together so as to form an equal number of equivalent equations of the exact form. Generally when we know this combination to be possible it is easy to effect it, and best to endeavour to do so. We might however employ the method of the variation of parameters as follows. Supposing  $p$  the number of differential equations make all but  $p + 1$  of the variables constant, integrate the reduced system, and then seek to satisfy the unreduced system by the same series of integrals with the arbitrary constants as new variables. The successive integrations and transformations of this method would amount to the same thing as those upon which the second part of the demonstration of Prop. III. rests\*.

Lastly, given a system of ordinary differential equations containing a superfluous number of variables without knowing how many integrals they admit, we must, supposing  $P = c$  to be *any* integral, construct the corresponding system

\* It was thus indeed that the author was first led to that theory.

of homogeneous partial differential equations satisfied by  $P$ , and apply to them the foregoing Rule.

8. Ex. Required the integrals of the simultaneous partial differential equations

$$\frac{dP}{dx} + (t + xy + xz) \frac{dP}{dz} + (y + z - 3x) \frac{dP}{dt} = 0,$$

$$\frac{dP}{dy} + (xzt + y - xy) \frac{dP}{dz} + (zt - y) \frac{dP}{dt} = 0.$$

Representing these in the form  $\Delta_1 P = 0$ ,  $\Delta_2 P = 0$ , it will be found that the equation

$$(\Delta_1 \Delta_2 - \Delta_2 \Delta_1) P = 0$$

becomes, after rejecting an algebraic factor,

$$x \frac{dP}{dz} + \frac{dP}{dt} = 0,$$

and the three equations prepared in the manner explained in the Rule will be found to be

$$\frac{dP}{dx} + (3x^2 + t) \frac{dP}{dz} = 0,$$

$$\frac{dP}{dy} + y \frac{dP}{dz} = 0,$$

$$\frac{dP}{dt} + x \frac{dP}{dz} = 0.$$

No other equations are derivable from these. We conclude that there is but one final integral.

To obtain it, eliminate

$$\frac{dP}{dx}, \quad \frac{dP}{dy}, \quad \frac{dP}{dt}$$

from the above system combined with

$$\frac{dP}{dx}dx + \frac{dP}{dy}dy + \frac{dP}{dz}dz + \frac{dP}{dt}dt = 0,$$

and equate to 0 the coefficient of  $\frac{dP}{dz}$  in the result. We find

$$dz - (t + 3x^2)dx - ydy - xdt = 0,$$

the integral of which is

$$z - xt - x^3 - \frac{y^2}{2} = c.$$

An arbitrary function of the first member of this equation is the general value of  $P$ .

[It appears from the manuscript that another example was to have been added here.]

## CHAPTER XXVI.

## HOMOGENEOUS SYSTEMS OF LINEAR PARTIAL DIFFERENTIAL EQUATIONS.

1. THE theory of homogeneous systems of linear partial differential equations in which when expressed in the symbolic form

$$\Delta_1 P = 0, \quad \Delta_2 P = 0, \dots \Delta_m P = 0 \dots \dots (1),$$

the condition

$$(\Delta_i \Delta_j - \Delta_j \Delta_i) P = 0 \dots \dots \dots (2)$$

is for all combinations represented by  $i$  and  $j$  satisfied in virtue of the constitution of the symbols  $\Delta_i, \Delta_j$ , forms the subject of important researches by Jacobi (*Nova Methodus...* Crelle's Journal, Vol. LX. p. 1). The following are the most important of his results.

1st. An integral of any one equation of the system being found, other integrals of the same system may be obtained without integration, by a process of derivation founded upon the condition (2).

Let  $\phi$  be an integral of the first equation of the system. Then is the equation

$$\Delta_1 \phi = 0$$

identically satisfied.

Also the condition (2) being satisfied in virtue of the constitution of the symbols, we have

$$(\Delta_i \Delta_j - \Delta_j \Delta_i) \phi = 0;$$

and in particular, making  $i = 1$ , and separating the terms,

$$\Delta_1 \Delta_j \phi - \Delta_j \Delta_1 \phi = 0,$$

which reduces by a prior equation to

$$\Delta_1 \Delta_j \phi = 0.$$

It appears from this that  $\Delta_j \phi$ , if it do not reduce to a constant, is an integral of the first equation  $\Delta_1 \phi = 0$ , and, if it prove to be not a mere function of  $\phi$ , a new integral.

This process may be repeated upon the new integral with a similar alternation of results. It will be evident from this that if we confine our attention to the two equations

$$\Delta_1 P = 0, \quad \Delta_2 P = 0,$$

and suppose, as before,  $\phi$  to be an integral of the first, then will

$$\Delta_2 \phi, \quad \Delta_2 (\Delta_2 \phi), \quad \Delta_2 \{\Delta_2 (\Delta_2 \phi)\}, \dots$$

or, as these may be expressed,

$$\Delta_2 \phi, \quad \Delta_2^2 \phi, \quad \Delta_2^3 \phi, \dots$$

be also integrals of the first equation; and this process of derivation may be continued until we arrive at an integral  $\Delta_2^\mu \phi$  which is not independent, but is expressible as a function of prior integrals

$$\Delta_2 \phi, \quad \Delta_2^2 \phi, \dots \Delta_2^{\mu-1} \phi,$$

and, sooner or later, such a result must present itself, since the number of independent integrals is finite.

It is further seen that the most general symbolic form of an integral derivable from the root integral  $\phi$  is

$$\Delta_2^\alpha \Delta_3^\beta \dots \Delta_m^\mu \phi,$$

$\alpha, \beta, \dots, \mu$ , being positive integers.

The above remarkable theorem was in some degree anticipated by the researches of Poisson.

2ndly. Jacobi shews how by the aid of such derived integrals of the first equation of the system a *common* integral of the first and second equation may be found, and how from this integral and its derived series a common integral of the first three equations of the system may be found, and so on, until a common integral of the entire system has been as it were built up out of previous integrals of less general application.

Let  $\phi, \phi', \phi'', \dots \phi^{(\mu-1)}$  represent a series of independent integrals of the equation  $\Delta_1 P = 0$ , of which  $\phi$  is the root integral, and the rest are derived from it by successive applications of the operation denoted by  $\Delta_2$ , so that

$$\phi' = \Delta_2 \phi, \dots \phi^{(\mu-1)} = \Delta_2^{\mu-1} \phi;$$

also let  $\Delta_2^\mu \phi$  be not a new integral but a function of

$$\phi, \phi', \dots \phi^{(\mu-1)}.$$

Now  $\phi, \phi', \dots \phi^{(\mu-1)}$  being particular integrals of  $\Delta_1 P = 0$ , the function  $F(\phi, \phi', \dots \phi^{(\mu-1)})$  will also be an integral of the same equation *irrespective of its form*. Let us inquire whether the form of the function can be so determined as to render it also an integral of the second equation  $\Delta_2 P = 0$ .

We have then to satisfy the equation

$$\Delta_2 F(\phi, \phi', \dots \phi^{(\mu-1)}) = 0.$$

By the principles of the Differential Calculus this equation assumes the form

$$\Delta_2 \phi \frac{dF}{d\phi} + \Delta_2 \phi' \frac{dF}{d\phi'} + \dots + \Delta_2 \phi^{(\mu-1)} \frac{dF}{d\phi^{(\mu-1)}} = 0.$$

But  $\Delta_2 \phi = \phi', \Delta_2 \phi' = \phi'', \dots \Delta_2 \phi^{(\mu-2)} = \phi^{(\mu-1)};$

lastly,  $\Delta_2 \phi^{(\mu-1)}$  may by hypothesis be expressed in the form  $f(\phi, \phi', \dots \phi^{(\mu-1)})$ . Thus the equation to be satisfied is

$$\phi' \frac{dF}{d\phi} + \phi'' \frac{dF}{d\phi'} + \dots + \phi^{(\mu-1)} \frac{dF}{d\phi^{(\mu-2)}} + f(\phi, \phi', \dots, \phi^{(\mu-1)}) \frac{dF}{d\phi^{(\mu-1)}} = 0,$$

a linear partial differential equation of which the auxiliary system is

$$\frac{d\phi}{\phi'} = \frac{d\phi'}{\phi''} = \dots = \frac{d\phi^{(\mu-2)}}{\phi^{(\mu-1)}} = \frac{d\phi^{(\mu-1)}}{f(\phi, \phi', \dots, \phi^{(\mu-1)})} \dots (3).$$

Now the integration of this system may be made to depend upon that of an ordinary differential equation of the  $(\mu - 1)^{\text{th}}$  degree between the two variables  $\phi^{(\mu-1)}$  and  $\phi$ .

For we have

$$\begin{aligned} \frac{d\phi'}{d\phi} &= \frac{\phi''}{\phi'}, \dots, \frac{d\phi^{(\mu-2)}}{d\phi} = \frac{\phi^{(\mu-1)}}{\phi'}, \\ \frac{d\phi^{(\mu-1)}}{d\phi} &= \frac{f(\phi, \phi', \dots, \phi^{(\mu-1)})}{\phi'}. \end{aligned}$$

Differentiating the last equation with respect to  $\phi$ , and attending to the former ones, we shall be able to express  $\frac{d^2\phi^{(\mu-1)}}{d\phi^2}$  in terms of the variables  $\phi, \phi', \dots, \phi^{(\mu-1)}$ . Proceeding with this in the same way and continuing the process we shall be able to express the series of differential coefficients

$$\frac{d\phi^{(\mu-1)}}{d\phi}, \frac{d^2\phi^{(\mu-1)}}{d\phi^2}, \dots, \frac{d^{\mu-1}\phi^{(\mu-1)}}{d\phi^{\mu-1}}$$

in terms of  $\phi, \phi', \dots, \phi^{(\mu-1)}$ . From these  $\mu - 1$  equations, eliminating  $\phi', \phi'', \dots, \phi^{(\mu-2)}$ , we shall have a final equation between

$$\phi, \phi^{(\mu-1)}, \frac{d\phi^{(\mu-1)}}{d\phi}, \dots, \frac{d^{\mu-1}\phi^{(\mu-1)}}{d\phi^{\mu-1}},$$

that is, a differential equation of the  $(\mu - 1)^{\text{th}}$  order between  $\phi$  and  $\phi^{(\mu-1)}$ .

The complete integral of this equation will be of the form

$$\phi^{(\mu-1)} = f(\phi, c_1, c_2, \dots, c_{\mu-1}).$$

Differentiating this  $\mu - 2$  times in succession with respect to  $\phi$ , and continually substituting for the differential coefficients of  $\phi^{(\mu-1)}$  their values as before assigned in terms of

$$\phi, \phi', \dots, \phi^{(\mu-1)},$$

we shall have a system of  $\mu - 1$  equations connecting the above variables with the constants  $c_1, c_2, \dots, c_{\mu-1}$ . Finally, solving these equations with respect to the constants, we shall possess the integrals required in the form

$$F_1(\phi, \phi', \dots, \phi^{(\mu-1)}) = c_1,$$

$$\dots\dots\dots$$

$$F_{\mu-1}(\phi, \phi', \dots, \phi^{(\mu-1)}) = c_{\mu-1},$$

and each of these will be a common integral of the first two equations of the given system (1).

[On the back of a page of the manuscript the following paragraph occurs, which seems to have been intended as a simplification of the preceding argument which begins with "The complete integral."]

Suppose that a first integral of the equation can be found. Its form will be

$$F\left(\phi, \phi^{(\mu-1)}, \frac{d\phi^{(\mu-1)}}{d\phi}, \dots, \frac{d^{\mu-2}\phi^{(\mu-1)}}{d\phi^{\mu-2}}\right) = c.$$

Substitute in this for the differential coefficients of  $\phi^{(\mu-1)}$  their values before assigned in terms of  $\phi, \phi', \phi'', \dots, \phi^{(\mu-1)}$ , and we have an integral of the system (3), and therefore a common integral of the first two equations of the system (1).

[We now return to the place at which we inserted a paragraph.]

Just in the same way Jacobi deduces a common integral of the first three equations of the system (1). For representing

any one of the first members of the above system by  $\psi$ , and deriving thence the new independent integrals  $\Delta_3\psi$ ,  $\Delta_3^2\psi$ ,... he substitutes an arbitrary function of these for  $P$  in the equation

$$\Delta_3 P = 0.$$

It is evident that the solution of the partial differential equation so found will again be reducible to that of an ordinary differential equation between two variables. And so the process is carried on till all the equations are satisfied.

2. The above remarkable process was developed by Jacobi in connexion with the theory of non-linear partial differential equations of the first order. In that particular connexion it admits of certain reductions tending to diminish the order of the differential equations to be integrated. But these do not affect the general principle of the method. It was in this special form that the theory of the solution of simultaneous linear partial differential equations originated. Jacobi does not consider the theory of equations in which the condition (2) is not satisfied; but the language in which he refers to the condition shews that he had speculated upon the general problem—and it is difficult to conceive that he should have meditated upon it and not arrived at its complete solution.

[The manuscript here gives the first two words of the passage from Jacobi's memoir which is quoted in the *Philosophical Transactions* for 1863, page 486.]

## CHAPTER XXVII.

OF NON-LINEAR PARTIAL DIFFERENTIAL EQUATIONS OF THE  
FIRST ORDER.

1. IN treating the present subject we shall first consider that class of non-linear partial differential equations of the first order which involves two independent variables, and then proceed to the general theory. The reason for this procedure is that the particular theory, though of course included in the general one, rests upon a somewhat simpler basis, and it was in fact developed by the labours of Lagrange and Charpit long before the general theory was known. The latter we owe to the independent researches of Cauchy and Jacobi.

[Here the manuscript refers to the matter contained in Chap. XIV. Arts. 7 to 12 inclusive; and then passes on to the general theory.]

*General Theory.*

2. Given an equation of the form

$$z = \phi(x_1, x_2, \dots x_n, a_1, a_2, \dots a_n),$$

the number of arbitrary constants  $a_1, a_2, \dots a_n$  involved being equal to the number of the independent variables  $x_1, x_2, \dots x_n$ , we obtain by differentiation and elimination of the constants a partial differential equation of the first order. Of this the proposed equation is said to constitute a complete primitive.

Examining the system (3), (4) we see that the first members of all the equations which it contains are functions of  $x_1, \dots x_n, z, p_1, \dots p_n$ , while the second members are constants. The question then arises, What mutual connexion exists among these functions in virtue of which they yield values of  $p_1, \dots p_n$ , which render the equation (5) integrable?

The answer to this question must involve the entire theory of the solution of partial differential equations of the first order, so far as relates to the determination of a complete primitive. Given a partial differential equation of the form (3) it is evident that if we can construct a system of associated equations (4) possessing the character above described, the final value of  $z$  obtained by integration of (5) will both satisfy the given equation and contain the requisite number of arbitrary constants. It does not follow from this that it will be the only complete primitive, but it will be a complete primitive.

3. The relation sought is expressed in the following Proposition:

PROPOSITION. *If*

$$F(x_1, \dots x_n, z, p_1, \dots p_n) = a,$$

$$\Phi(x_1, \dots x_n, z, p_1, \dots p_n) = b$$

*represent any two out of a system of  $n$  independent equations such that the values of  $p_1, \dots p_n$ , thence determined would make the equation*

$$dz = p_1 dx_1 + p_2 dx_2 + \dots + p_n dx_n$$

*integrable, then the first members of these equations being represented for simplicity by  $F$  and  $\Phi$ , the condition*

$$\sum_i \left\{ \left( \frac{dF}{dx_i} + p_i \frac{dF}{dz} \right) \frac{d\Phi}{dp_i} - \frac{dF}{dp_i} \left( \frac{d\Phi}{dx_i} + p_i \frac{d\Phi}{dz} \right) \right\} = 0,$$

*the summation extending to all values of  $i$ , from 1 to  $n$  inclusive, will be satisfied identically.*

*Reciprocally, if the above condition be satisfied identically for each binary combination of functions in the proposed system of equations, and if these functions be independent, then the values of  $p_1, \dots, p_n$ , as functions of  $x_1, \dots, x_n, z$ , which they yield, will make the equation*

$$dz = p_1 dx_1 + p_2 dx_2 + \dots + p_n dx_n$$

*integrable.*

It will be convenient to begin with the particular case in which the proposed equations do not explicitly contain  $z$ , the particular pair to be considered being represented by

$$F(x_1, \dots, x_n, p_1, \dots, p_n) = a,$$

$$\Phi(x_1, \dots, x_n, p_1, \dots, p_n) = b.$$

Differentiating with respect to  $x_i$ , and regarding  $p_1, \dots, p_n$  as functions of the independent variables, we have

$$\left. \begin{aligned} \frac{dF}{dx_i} + \frac{dF}{dp_1} \frac{dp_1}{dx_i} + \dots + \frac{dF}{dp_n} \frac{dp_n}{dx_i} &= 0, \\ \frac{d\Phi}{dx_i} + \frac{d\Phi}{dp_1} \frac{dp_1}{dx_i} + \dots + \frac{d\Phi}{dp_n} \frac{dp_n}{dx_i} &= 0, \end{aligned} \right\} \dots\dots\dots (6),$$

to which we may give the form

$$\left. \begin{aligned} \frac{dF}{dx_i} &= - \sum_j \frac{dF}{dp_j} \frac{dp_j}{dx_i} \\ \frac{d\Phi}{dx_i} &= - \sum_j \frac{d\Phi}{dp_j} \frac{dp_j}{dx_i} \end{aligned} \right\} \dots\dots\dots (7),$$

the summation with respect to  $j$  extending from  $j=1$  to  $j=n$  inclusive.

From the first of equations (7) multiplied by  $\frac{d\Phi}{dp_i}$  subtract

the second multiplied by  $\frac{dF}{dp_i}$ , and sum the result with respect to  $i$  from  $i=1$  to  $i=n$  inclusive. We have

$$\begin{aligned} \sum_i \left( \frac{dF}{dx_i} \frac{d\Phi}{dp_i} - \frac{dF}{dp_i} \frac{d\Phi}{dx_i} \right) \\ = - \sum_i \sum_j \left( \frac{dF}{dp_j} \frac{d\Phi}{dp_i} \frac{dp_j}{dx_i} - \frac{dF}{dp_i} \frac{d\Phi}{dp_j} \frac{dp_j}{dx_i} \right) \dots\dots (8). \end{aligned}$$

The expression under the double sign of summation in the second member vanishes when  $i=j$ ; we may therefore restrict the summation to unequal values of  $i$  and  $j$ . Now as for any particular combination of values, e.g. 2, 3, there would exist in the completed member both the terms corresponding to  $i=2, j=3$ , and those corresponding to  $j=2, i=3$ , it is evident that if we employ the symbol  $\sum_{ij}$  to denote summation with respect to different combinations of  $i$  and  $j$ , the second member of the last equation may be expressed in the form

$$\begin{aligned} \sum_{ij} \left( \frac{dF}{dp_j} \frac{d\Phi}{dp_i} \frac{dp_j}{dx_i} - \frac{dF}{dp_i} \frac{d\Phi}{dp_j} \frac{dp_j}{dx_i} \right. \\ \left. + \frac{dF}{dp_i} \frac{d\Phi}{dp_j} \frac{dp_i}{dx_j} - \frac{dF}{dp_j} \frac{d\Phi}{dp_i} \frac{dp_i}{dx_j} \right), \\ \text{or } \sum_{ij} \left\{ \left( \frac{dF}{dp_i} \frac{d\Phi}{dp_j} - \frac{dF}{dp_j} \frac{d\Phi}{dp_i} \right) \left( \frac{dp_i}{dx_j} - \frac{dp_j}{dx_i} \right) \right\}, \end{aligned}$$

so that the equation (8) becomes

$$\begin{aligned} \sum_i \left( \frac{dF}{dx_i} \frac{d\Phi}{dp_i} - \frac{dF}{dp_i} \frac{d\Phi}{dx_i} \right) \\ = - \sum_{ij} \left\{ \left( \frac{dF}{dp_i} \frac{d\Phi}{dp_j} - \frac{dF}{dp_j} \frac{d\Phi}{dp_i} \right) \left( \frac{dp_i}{dx_j} - \frac{dp_j}{dx_i} \right) \right\} \dots\dots (9). \end{aligned}$$

The number of terms of which the second member expresses the sum is thus  $\frac{n(n-1)}{2}$ , and it will be observed that

as to any particular term it makes no difference in what order the numerical values of  $i$  and  $j$  are assigned to these quantities; e.g. whether for the combination 2, 3 we make  $i=2$ ,  $j=3$ , or  $i=3$ ,  $j=2$ ; but we must confine ourselves to one order.

Now when the equation

$$dz = p_1 dx_1 + p_2 dx_2 + \dots + p_n dx_n$$

is integrable in the manner here supposed, we have for all combinations of  $i$  and  $j$ ,

$$\frac{dp_i}{dx_j} = \frac{dp_j}{dx_i}.$$

All the terms in the second member of (9) therefore vanish, and we have

$$\sum_i \left( \frac{dF}{dx_i} \frac{d\Phi}{dp_i} - \frac{dF}{dp_i} \frac{d\Phi}{dx_i} \right) = 0.$$

This is the direct form of the Proposition under the particular limitation supposed.

As  $F$ ,  $\Phi$  represent, under the same limitation, any two of the first members of the  $n$  equations (3), (4), which determine  $p_1, \dots, p_n$ , there will exist  $\frac{n(n-1)}{2}$  equations like the above.

It is usual to employ for brevity the notation

$$\sum_i \left( \frac{dF}{dx_i} \frac{d\Phi}{dp_i} - \frac{dF}{dp_i} \frac{d\Phi}{dx_i} \right) = [F\Phi],$$

and this being done the above system of equations expresses the  $\frac{n(n-1)}{2}$  functions of the form  $[F_i F_j]$  as linear homogeneous

functions of the  $\frac{n(n-1)}{2}$  quantities of the form  $\frac{dp_i}{dx_j} - \frac{dp_j}{dx_i}$ .

It is hence that the vanishing of the latter series of quantities secures the vanishing of the former.

The converse truth will therefore be established by shewing that the  $\frac{n(n-1)}{2}$  quantities of the form  $\frac{dp_i}{dx_j} - \frac{dp_j}{dx_i}$  are, when

$F_1, F_2, \dots, F_n$  are independent with respect to  $p_1, p_2, \dots, p_n$ , expressible as linear homogeneous functions of the  $\frac{n(n-1)}{2}$  functions  $[F_i F_j]$ .

To avoid complexity of expression I shall establish this for the particular case of  $n=3$ , and shall shew that the reasoning is general.

The functions  $F_1, F_2, F_3$ , being independent with respect to  $p_1, p_2, p_3$ , the determinant

$$\begin{vmatrix} \frac{dF_1}{dp_1}, & \frac{dF_1}{dp_2}, & \frac{dF_1}{dp_3} \\ \frac{dF_2}{dp_1}, & \frac{dF_2}{dp_2}, & \frac{dF_2}{dp_3} \\ \frac{dF_3}{dp_1}, & \frac{dF_3}{dp_2}, & \frac{dF_3}{dp_3} \end{vmatrix}$$

does not vanish. This determinant we shall denote by  $\Delta$ .

In (9) writing for  $F$  and  $\Phi$  first  $F_2$  and  $F_3$ , secondly  $F_3$  and  $F_1$ , thirdly  $F_1$  and  $F_2$ , we have on changing signs the system

$$\left. \begin{aligned} -[F_2 F_3] &= \left( \frac{dF_2}{dp_2} \frac{dF_3}{dp_3} - \frac{dF_2}{dp_3} \frac{dF_3}{dp_2} \right) \left( \frac{dp_2}{dx_3} - \frac{dp_3}{dx_2} \right) + \dots \\ -[F_3 F_1] &= \left( \frac{dF_3}{dp_2} \frac{dF_1}{dp_3} - \frac{dF_3}{dp_3} \frac{dF_1}{dp_2} \right) \left( \frac{dp_2}{dx_3} - \frac{dp_3}{dx_2} \right) + \dots \\ -[F_1 F_2] &= \left( \frac{dF_1}{dp_2} \frac{dF_2}{dp_3} - \frac{dF_1}{dp_3} \frac{dF_2}{dp_2} \right) \left( \frac{dp_2}{dx_3} - \frac{dp_3}{dx_2} \right) + \dots \end{aligned} \right\} \quad (10).$$

Multiply the first equation by  $\frac{dF_1}{dp_1}$ , the second by  $\frac{dF_2}{dp_1}$ , the third by  $\frac{dF_3}{dp_1}$  and add. Then

$$-\frac{dF_1}{dp_1} [F_2 F_3] - \frac{dF_2}{dp_1} [F_3 F_1] - \frac{dF_3}{dp_1} [F_1 F_2] = \Delta \left( \frac{dp_2}{dx_3} - \frac{dp_3}{dx_2} \right),$$

whence as  $\Delta$  does not vanish we have, on dividing by it, the function  $\frac{dp_2}{dx_3} - \frac{dp_3}{dx_2}$  expressed as a linear homogeneous function of  $[F_2F_3]$ ,  $[F_3F_1]$ , and  $[F_1F_2]$ .

In like manner multiplying the equations by  $\frac{dF_1}{dp_2}$ ,  $\frac{dF_2}{dp_2}$ ,  $\frac{dF_3}{dp_2}$  respectively, and dividing by  $\Delta$ , we obtain  $\frac{dp_3}{dx_1} - \frac{dp_1}{dx_3}$  as a similar linear homogeneous function, and lastly, multiplying by  $\frac{dF_1}{dp_3}$ ,  $\frac{dF_2}{dp_3}$ ,  $\frac{dF_3}{dp_3}$ , and proceeding as before, we obtain  $\frac{dp_1}{dx_2} - \frac{dp_2}{dx_1}$  as a similar linear homogeneous function.

From all which it follows that when  $[F_2F_3]$ ,  $[F_3F_1]$ ,  $[F_1F_2]$  vanish, then

$$\frac{dp_2}{dx_3} - \frac{dp_3}{dx_2}, \quad \frac{dp_3}{dx_1} - \frac{dp_1}{dx_3}, \quad \frac{dp_1}{dx_2} - \frac{dp_2}{dx_1},$$

will vanish also.

The reasoning is general in its nature. If  $F_1, F_2, \dots, F_n$  are independent with regard to  $p_1, p_2, \dots, p_n$ , the determinant

$$\begin{vmatrix} \frac{dF_1}{dp_1} & \dots & \frac{dF_1}{dp_n} \\ \dots & \dots & \dots \\ \frac{dF_n}{dp_1} & \dots & \frac{dF_n}{dp_n} \end{vmatrix} = \Delta \dots \dots \dots (11),$$

does not vanish. This determinant is from its constitution as a determinant linear and homogeneous, not only with respect to any row or column of elements, but also with respect to the possible binary combinations which can be formed of two rows or columns, ternary out of three rows or columns, &c. provided that these combinations are themselves of the form of determinants. In the language of the theory such combinations are called minor determinants. Hence if we construct the system of equations represented by (10), and

observe that the coefficients of any particular term of the form  $\frac{dp_i}{dx_j} - \frac{dp_j}{dx_i}$  in the several equations form a system of such minors to the general determinant (11), it will be plain that the equations can by multiplication and addition be brought to a form in which the coefficient of that particular term will be  $\Delta$ . At the same time the coefficients of all the other terms of the form  $\frac{dp_i}{dx_j} - \frac{dp_j}{dx_i}$  will vanish. For a little attention will shew that they will be what the determinant  $\Delta$  would become on making two of its columns or rows of elements equal, and therefore will be identically equal to 0.

Thus the Proposition is generally established for the case in which  $z$  does not explicitly appear in the functions

$$F_1, F_2, \dots, F_n.$$

When  $z$  does appear in those functions the equations (6) will be replaced by

$$\frac{dF}{dx_i} + p_i \frac{dF}{dz} + \frac{dF}{dp_1} \frac{dp_1}{dx_i} + \dots + \frac{dF}{dp_n} \frac{dp_n}{dx_i} = 0,$$

$$\frac{d\Phi}{dx_i} + p_i \frac{d\Phi}{dz} + \frac{d\Phi}{dp_1} \frac{dp_1}{dx_i} + \dots + \frac{d\Phi}{dp_n} \frac{dp_n}{dx_i} = 0,$$

from which it is seen that the theorem above established will only need to be changed into the form employed in the statement of the general Proposition.

As the above is one of the most important propositions in the entire theory of Differential Equations, it may be desirable to illustrate it by examples.

[There are no examples in the manuscript.]

4. We resume the general theory.

The integration of non-linear partial differential equations may be effected by two distinct methods, both resting upon

the ground of the above Proposition. The first of these methods, originally established by a different analysis from that which will here be employed, was discovered by Cauchy (*Exercices d'Analyse*), and rediscovered by Jacobi (*Crelle's Journal*). The second method, discovered by Jacobi at a later period, forms the subject of his posthumous memoir, *Nova Methodus*.....

### *Cauchy's Method.*

We will, as before, begin with the case in which  $z$  does not appear explicitly in the proposed partial differential equation, which we shall represent in the form

$$F_1(x_1, \dots x_n, p_1, \dots p_n) = 0 \dots\dots\dots (1).$$

We have seen that to find a complete primitive of the equation it is necessary and sufficient to construct a series of equations

$$\left. \begin{array}{l} F_2(x_1, \dots x_n, p_1, \dots p_n) = \alpha_2 \\ \dots\dots\dots \\ F_n(x_1, \dots x_n, p_1, \dots p_n) = \alpha_n \end{array} \right\} \dots\dots\dots (2),$$

such that not only shall the conditions

$$[F_1 F_2] = 0, \dots\dots [F_1 F_n] = 0 \dots\dots\dots (3),$$

connecting the new functions  $F_2, \dots F_n$  with  $F_1$ , be identically satisfied, but also the series of conditions

$$[F_a F_b] = 0 \dots\dots\dots (4),$$

$F_a$  and  $F_b$  representing any two of the new functions referred to.

The first of the above series of conditions amounts to this, that  $F_2, \dots F_n$  must be integrals of the partial differential equation

$$[F_1 F] = 0 \dots\dots\dots (5).$$

It is the peculiar aim of Cauchy's method to determine the integrals so as to cause the second series of conditions to be satisfied also. And it is shewn that this will be attained if the integrals of (5), which form the first members of (2), are such that the particular values which  $p_1, \dots, p_{n-1}$  assume when  $x_n$  is made to receive any constant value, as 0, are differential coefficients with respect to  $x_1, \dots, x_{n-1}$  of any single function of those variables, the form of which may be arbitrarily assigned.

The *necessity* of this condition is obvious. If the general values of  $p_1, \dots, p_n$  are differential coefficients of a function  $z$  with respect to  $x_1, \dots, x_n$ , then the particular forms which  $p_1, \dots, p_{n-1}$  assume when  $x_n$  receives any constant value are simply differential coefficients with respect to  $x_1, \dots, x_{n-1}$  of what  $z$  becomes under the same circumstances. To prove its *sufficiency* we must shew that when it is satisfied the conditions represented by (4) will be satisfied also.

Since  $F_a$  and  $F_b$  are integrals of  $[F_1 P] = 0$ ,

$$[F_1 F_a] = 0, \quad [F_1 F_b] = 0 \dots\dots\dots(6).$$

Also, since if in (1) and (2) we give to  $x_n$  a particular constant value, as 0, and then in (2) regard  $p_n$  as a function of

$$x_1, \dots, x_{n-1}, \quad p_1, \dots, p_{n-1}$$

determined by (1), the system (2) will virtually contain only

$$x_1, \dots, x_{n-1}, \quad p_1, \dots, p_{n-1},$$

of which  $p_1, \dots, p_{n-1}$  are differential coefficients of a single function with respect to  $x_1, \dots, x_{n-1}$ , it follows from the proposition of Art. 3, that any two functions  $F_a$  and  $F_b$  will satisfy mutually the condition

$$\sum_{i=1}^{n-1} \left( \frac{dF_a}{dx_i} \frac{dF_b}{dp_i} - \frac{dF_a}{dp_i} \frac{dF_b}{dx_i} \right) = 0,$$

the differentiations having reference to

$$x_1, \dots, x_{n-1}, \quad p_1, \dots, p_{n-1},$$

explicitly as they appear in  $F_a$  and  $F_b$ , and implicitly as involved in  $p_n$ . Thus the developed form of the above equation is

$$\sum_{i=1}^{i=n-1} \left\{ \left( \frac{dF_a}{dx_i} + \frac{dF_a}{dp_n} \frac{dp_n}{dx_i} \right) \left( \frac{dF_b}{dp_i} + \frac{dF_b}{dp_n} \frac{dp_n}{dp_i} \right) - \left( \frac{dF_a}{dp_i} + \frac{dF_a}{dp_n} \frac{dp_n}{dp_i} \right) \left( \frac{dF_b}{dx_i} + \frac{dF_b}{dp_n} \frac{dp_n}{dx_i} \right) \right\} = 0,$$

the forms of  $\frac{dp_n}{dx_i}$  and  $\frac{dp_n}{dp_i}$  being determined from (1).

Performing the multiplications, the above equations will be reduced to the form

$$\begin{aligned} & \sum_{i=1}^{i=n-1} \left( \frac{dF_a}{dx_i} \frac{dF_b}{dp_i} - \frac{dF_a}{dp_i} \frac{dF_b}{dx_i} \right) \\ & + \frac{dF_a}{dp_n} \sum_{i=1}^{i=n-1} \left( \frac{dp_n}{dx_i} \frac{dF_b}{dp_i} - \frac{dp_n}{dp_i} \frac{dF_b}{dx_i} \right) \\ & - \frac{dF_b}{dp_n} \sum_{i=1}^{i=n-1} \left( \frac{dp_n}{dx_i} \frac{dF_a}{dp_i} - \frac{dp_n}{dp_i} \frac{dF_a}{dx_i} \right) = 0 \dots (7). \end{aligned}$$

But from the form of the total differential of (1) we see that

$$\frac{dp_n}{dx_i} = - \frac{\frac{dF_1}{dx_i}}{\frac{dF_1}{dp_n}}, \quad \frac{dp_n}{dp_i} = - \frac{\frac{dF_1}{dp_i}}{\frac{dF_1}{dp_n}}.$$

Hence

$$\begin{aligned} & \sum_{i=1}^{i=n-1} \left( \frac{dp_n}{dx_i} \frac{dF_a}{dp_i} - \frac{dp_n}{dp_i} \frac{dF_a}{dx_i} \right) \\ & = - \left( \frac{dF_1}{dp_n} \right)^{-1} \sum_{i=1}^{i=n-1} \left( \frac{dF_1}{dx_i} \frac{dF_a}{dp_i} - \frac{dF_1}{dp_i} \frac{dF_a}{dx_i} \right). \end{aligned}$$

Now since by Art. 3

$$\sum_{i=1}^{i=n} \left( \frac{dF_1}{dx_i} \frac{dF_a}{dp_i} - \frac{dF_1}{dp_i} \frac{dF_a}{dx_i} \right) = 0,$$

we have

$$\begin{aligned} \sum_{i=1}^{i=n-1} \left( \frac{dF_1}{dx_i} \frac{dF_a}{dp_i} - \frac{dF_1}{dp_i} \frac{dF_a}{dx_i} \right) \\ = - \left( \frac{dF_1}{dx_n} \frac{dF_a}{dp_n} - \frac{dF_1}{dp_n} \frac{dF_a}{dx_n} \right); \end{aligned}$$

therefore

$$\begin{aligned} \sum_{i=1}^{i=n-1} \left( \frac{dp_n}{dx_i} \frac{dF_a}{dp_i} - \frac{dp_n}{dp_i} \frac{dF_a}{dx_i} \right) \\ = \left( \frac{dF_1}{dp_n} \right)^{-1} \left( \frac{dF_1}{dx_n} \frac{dF_a}{dp_n} - \frac{dF_1}{dp_n} \frac{dF_a}{dx_n} \right). \end{aligned}$$

In the same way

$$\begin{aligned} \sum_{i=1}^{i=n-1} \left( \frac{dp_n}{dx_i} \frac{dF_b}{dp_i} - \frac{dp_n}{dp_i} \frac{dF_b}{dx_i} \right) \\ = \left( \frac{dF_1}{dp_n} \right)^{-1} \left( \frac{dF_1}{dx_n} \frac{dF_b}{dp_n} - \frac{dF_1}{dp_n} \frac{dF_b}{dx_n} \right). \end{aligned}$$

The substitution of these values in (7) gives

$$\begin{aligned} \sum_{i=1}^{i=n-1} \left( \frac{dF_a}{dx_i} \frac{dF_b}{dp_i} - \frac{dF_a}{dp_i} \frac{dF_b}{dx_i} \right) \\ + \left( \frac{dF_1}{dp_n} \right)^{-1} \left\{ \frac{dF_a}{dp_n} \left( \frac{dF_1}{dx_n} \frac{dF_b}{dp_n} - \frac{dF_1}{dp_n} \frac{dF_b}{dx_n} \right) \right. \\ \left. - \frac{dF_b}{dp_n} \left( \frac{dF_1}{dx_n} \frac{dF_a}{dp_n} - \frac{dF_1}{dp_n} \frac{dF_a}{dx_n} \right) \right\} = 0, \end{aligned}$$

$$\text{or} \quad \sum_{i=1}^{n-1} \left( \frac{dF_a}{dx_i} \frac{dF_b}{dp_i} - \frac{dF_a}{dp_i} \frac{dF_b}{dx_i} \right) + \frac{dF_a}{dx_n} \frac{dF_b}{dp_n} - \frac{dF_a}{dp_n} \frac{dF_b}{dx_n} = 0,$$

$$\text{or} \quad \sum_{i=1}^n \left( \frac{dF_a}{dx_i} \frac{dF_b}{dp_i} - \frac{dF_a}{dp_i} \frac{dF_b}{dx_i} \right) = 0,$$

which is precisely the equation

$$[F_a F_b] = 0.$$

We see therefore that to solve the partial differential equation

$$F_1(x, \dots, x_n, p_1, \dots, p_n) = 0,$$

it is only necessary to construct the linear partial differential equation

$$\sum_{i=1}^n \left( \frac{dF_1}{dx_i} \frac{dP}{dp_i} - \frac{dF_1}{dp_i} \frac{dP}{dx_i} \right) = 0,$$

and to obtain  $n - 1$  independent integrals of this

$$F_2(x_1, \dots, x_n, p_1, \dots, p_n) = a_2,$$

.....

$$F_n(x_1, \dots, x_n, p_1, \dots, p_n) = a_n,$$

such that if we determine from these conjoined with the given equation the values of  $p_1, \dots, p_n$ , then those of  $p_1, \dots, p_{n-1}$  shall, when  $x_n$  is made constant, be the partial differential coefficients of one and the same function of  $x_1, \dots, x_{n-1}$  with respect to these variables in succession.

Now provided that we can find *all* the integrals of the above partial differential equation the particular determination required may be effected in the following manner.

The Lagrangean auxiliary system consists of  $2n - 1$  ordinary differential equations

$$\frac{dx_1}{\frac{dF_1}{dp_1}} = \dots = \frac{dx_n}{\frac{dF_1}{dp_n}} = \frac{dp_1}{\frac{dF_1}{dx_1}} = \dots = \frac{dp_n}{\frac{dF_1}{dx_n}} \dots \dots \dots (8).$$

These admit of  $2n - 1$  integrals, one of which will be  $F_1 = c_1$ ; and this will agree with the given equation if we make  $c_1 = 0$ . We have therefore, besides the particular integral  $F_1 = 0$ ,  $2n - 2$  integrals of the form

$$\left. \begin{aligned} \phi_2(x_1, \dots, x_n, p_1, \dots, p_n) &= c_2 \\ &\dots\dots\dots \\ \phi_{2n-1}(x_1, \dots, x_n, p_1, \dots, p_n) &= c_{2n-1} \end{aligned} \right\} \dots\dots\dots (9).$$

Now suppose it required to find a value of  $z$  as a function of  $x_1, \dots, x_n$ , which shall satisfy the given partial differential equation, and shall reduce when  $x_n = 0$  (or any numerical constant) to a particular given function of  $x_1, \dots, x_{n-1}$ , which we will represent by  $\psi(x_1, \dots, x_{n-1})$ . Then on the assumption that  $x_n = 0$ , we have first the given equation

$$z = \psi(x_1, \dots, x_{n-1}) \dots\dots\dots (10),$$

secondly the derived equations

$$\left. \begin{aligned} p_1 &= \frac{d\psi(x_1, \dots, x_{n-1})}{dx_1} \\ &\dots\dots\dots \\ p_{n-1} &= \frac{d\psi(x_1, \dots, x_{n-1})}{dx_{n-1}} \end{aligned} \right\} \dots\dots\dots (11).$$

Make in the  $2n - 1$  integrals  $x_n = 0$ , and suppose at the same time  $x_1, \dots, x_{n-1}, p_1, \dots, p_{n-1}$  to receive therein the same values as in the above derived equations. Then from the  $3n - 2$  particular equations which we thus possess in the two systems united (particular because under the assumption that  $x_n = 0$ ), we can eliminate the  $2n - 1$  particular values of  $x_1, \dots, x_{n-1}, p_1, \dots, p_{n-1}$ , and so obtain  $n - 1$  equations among the constants. These express the conditions which are necessary and sufficient in order that the values of  $p_1, \dots, p_{n-1}$  thus derived from the integral equations may, when  $x_n = 0$ , agree with the values assigned in (11). Accordingly if we substitute in these equations of condition for  $c_2, \dots, c_{2n-1}$  the general values  $\phi_2, \dots, \phi_{2n-1}$  we shall obtain  $n - 1$  equations between  $x_1, \dots, x_n, p_1, \dots, p_n$ , which will at once be particular integrals of the system (8),

and will possess the property that the values of  $p_1, \dots p_{n-1}$  which they in conjunction with  $F_1 = 0$  give will when  $x_n = 0$  reduce to the values given in (11). Hence these values with that of  $p_n$  derived from the same equation will make

$$dz - p_1 dx_1 - \dots - p_n dx_n = 0$$

an exact differential equation. In the integral of this it will only remain to determine the constant so as to make the value of  $z$  agree with that given in (10). All the conditions will then be satisfied.

We may collect the results of the above investigation into the following Rule:

To obtain an expression for  $z$  as a function of the independent variables  $x_1, \dots x_n$ , which shall satisfy the partial differential equation

$$F(x_1, \dots x_n, p_1, \dots p_n) = 0,$$

and shall when  $x_n$  is made equal to 0 (or to any numerical value) reduce to a given function of  $x_1, \dots x_{n-1}$ , which we will represent by  $\psi(x_1, \dots x_{n-1})$ .

**RULE.** Construct the linear partial differential equation

$$\sum_{i=1}^n \left( \frac{dF}{dx_i} \frac{dP}{dp_i} - \frac{dF}{dp_i} \frac{dP}{dx_i} \right) = 0,$$

and forming its auxiliary Lagrangean system deduce its integrals

$$\phi_2 = c_2, \dots \quad \phi_{2n-1} = c_{2n-1},$$

in addition to the known particular integral  $F = 0$ .

Between the above integrals and the equations

$$p_1 = \frac{d\psi(x_1, \dots x_{n-1})}{dx_1}, \dots \quad p_{n-1} = \frac{d\psi(x_1, \dots x_{n-1})}{dx_{n-1}},$$

eliminate, after making  $x_n = 0$ , the quantities

$$x_1, \dots x_{n-1}, p_1, \dots p_{n-1}.$$

In the resulting  $n - 1$  equations replace

$$c_2 \text{ by } \phi_2, \dots c_{2n-1} \text{ by } \phi_{2n-1},$$

and we shall have a system of equations which with  $F=0$  will determine values of  $p_1, \dots p_n$ , which will render

$$dz - p_1 dx_1 - \dots - p_n dx_n$$

an exact differential. The integration of this will give the integral sought.

In the case in which the given partial differential equation is of the form

$$F(x_1, \dots x_n, z, p_1, \dots p_n) = 0,$$

$z$  being contained explicitly, the linear equation to be solved is

$$\sum_{i=1}^n \left\{ \left( \frac{dF}{dx_i} + p_i \frac{dF}{dz} \right) \frac{dP}{dp_i} - \frac{dF}{dp_i} \left( \frac{dP}{dx_i} + p_i \frac{dP}{dz} \right) \right\} = 0,$$

and the argument by which it is shewn that the integrals of this to be employed in conjunction with  $F=0$  for the determination of  $p_1, \dots p_n$  need only be so conditioned as to make  $p_1, \dots p_{n-1}$  differential coefficients of one and the same function of  $x_1, \dots x_{n-1}$  when  $x_n=0$  is in character the same as that already developed in the present Article. It is only necessary to substitute in its exposition  $\frac{dF}{dx_i} + p_i \frac{dF}{dz}$  for  $\frac{dF}{dx_i}$ , and so for the other functions.

But as the auxiliary system

$$\begin{aligned} \frac{\frac{dx_1}{dF}}{-\frac{dp_1}{dF}} &= \dots = \frac{\frac{dx_n}{dF}}{-\frac{dp_n}{dF}} = \frac{\frac{dz}{dF}}{-p_1 \frac{dF}{dp_1} - \dots - p_n \frac{dF}{dp_n}} \\ &= \frac{\frac{dp_1}{dF}}{\frac{dF}{dx_1} + p_1 \frac{dF}{dz}} = \dots = \frac{\frac{dp_n}{dF}}{\frac{dF}{dx_n} + p_n \frac{dF}{dz}} \dots \dots \quad (12) \end{aligned}$$

virtually includes the equation

$$dz - p_1 dx_1 - \dots - p_n dx_n = 0,$$

the ultimate expression of the Rule will be as follows:

To obtain an expression for  $z$  as a function of  $x_1, \dots x_n$  which shall satisfy the equation

$$F(x_1, \dots x_n, z, p_1, \dots p_n) = 0,$$

and shall when  $x_n$  is made equal to 0 (or to any particular constant value) reduce to a given function  $\psi(x_1, \dots x_{n-1})$  of the independent variables  $x_1, \dots x_{n-1}$ .

RULE. Let

$$\phi_2 = c_2, \dots \phi_{2n} = c_{2n}$$

be the  $2n - 1$  integrals of the auxiliary system (12) which are additional to the particular integral  $F=0$ . Make in these  $2n$  equations  $x_n=0$  and forming the further equations

$$\begin{aligned} z &= \psi(x_1, \dots x_{n-1}), \\ p_1 &= \frac{d\psi(x_1, \dots x_{n-1})}{dx_1}, \\ &\dots\dots\dots \\ p_{n-1} &= \frac{d\psi(x_1, \dots x_{n-1})}{dx_{n-1}}, \end{aligned}$$

eliminate the  $2n$  quantities  $x_1, \dots x_{n-1}, z, p_1, \dots p_n$ . We thus obtain  $n$  equations among the constants  $c_2, \dots c_{2n}$ .

Substitute in these equations  $\phi_2$  for  $c_2, \dots \phi_{2n}$  for  $c_{2n}$ , and we have  $n$  equations connecting  $x_1, \dots x_n, z, p_1, \dots p_n$ , from which with the aid of the given equation  $p_1, \dots p_n$  may be eliminated, and there will result a single equation connecting  $x_1, \dots x_n$  with  $z$ . This is the integral sought.

[It appears from the manuscript that an example was to have been supplied here.]

5. Cauchy's method is evidently a general one. But its generality is not of the same kind as that which belongs to Lagrange's solution of linear partial differential equations. It conducts us, not to a form embracing every possible

solution, but to a system of results from which every possible solution may be derived, by arbitrarily varying the form of the function which expresses the initial state of the dependent variable, that is the value of  $z$  when  $x_n = 0$ , and then performing certain eliminations. To obtain a complete primitive we should only have to assume as the form of  $z$  when  $x_n = 0$  a function of the variables  $x_1, \dots, x_{n-1}$  involving  $n$  independent constants. The form of this function is arbitrary. Each distinct determination of it under the conditions leads to a distinct complete primitive. The number of such complete primitives is infinite.

There are some most important problems in which the knowledge of a single complete primitive is all that is required. For this purpose the method of Jacobi which we shall now give may be employed.

### *Jacobi's Last Method.*

6. Supposing  $z$  to be not explicitly involved in the given partial differential equation

$$F_1(x_1, \dots, x_n, p_1, p_n) = 0,$$

which we shall as before represent by  $F_1 = 0$ , the problem of the discovery of a complete primitive consists in the finding of  $n - 1$  equations

$$F_2 = a_2, \dots, F_n = a_n,$$

such that between any two functions  $F_i F_j$  the relation

$$[F_i F_j] = 0 \dots \dots \dots (1)$$

shall be identically satisfied. The values of  $p_1, \dots, p_n$  deduced from the equations, by rendering

$$dz - p_1 dx_1 - \dots - p_n dx_n = 0$$

integrable lead us to the complete primitive expressed by its integral.

Now the idea upon which Jacobi's later methods rest is that of directly solving the different systems of linear partial differential equations flowing from the general condition (1), not of solving, as in Cauchy's method, one of those equations and then limiting that solution by conditions which virtually involve the satisfaction of the others.

It is evident that the entire series of  $\frac{n(n-1)}{2}$  conditions (1) will be satisfied if we determine  $F_2$  to satisfy the single equation

$$[F_1 F_2] = 0,$$

then  $F_3$  to satisfy the system of two simultaneous partial differential equations

$$[F_1 F_3] = 0, \quad [F_2 F_3] = 0,$$

then  $F_4$  to satisfy the system of three simultaneous partial differential equations

$$[F_1 F_4] = 0, \quad [F_2 F_4] = 0, \quad [F_3 F_4] = 0,$$

and so on, until finally  $F_n$  is determined by the solution of the system of  $n-1$  partial differential equations

$$[F_1 F_n] = 0, \quad [F_2 F_n] = 0, \quad \dots \dots [F_{n-1} F_n] = 0.$$

Now all these are particular cases of the general problem of determining a function  $P$  which shall satisfy simultaneously the equations

$$[F_1 P] = 0, \quad [F_2 P] = 0, \quad \dots \dots [F_n P] = 0. \quad (2)$$

$F_1, F_2, \dots F_n$  being given functions between each pair of which the equation

$$[F_i F_j] = 0$$

is identically satisfied. Here  $P$  will represent in succession the series  $F'_2, F'_3, \dots F'_n$ .

The given system is one of homogeneous linear partial differential equations. It belongs to the class of systems the

general theory of which is discussed in Chap. XXVI. But it is not necessary to apply the theory in its general form. We need only a *single* integral; for a single value of each of the functions  $F_2, F_3, \dots F_n$  suffices in combination with the given value of  $F_1$  for the determination of a complete primitive. Now it may be shewn that the system is of the class discussed in Chapter XXVI. If expressed symbolically in the form

$$\Delta_1 P = 0, \Delta_2 P = 0, \dots \Delta_n P = 0,$$

the condition

$$(\Delta_i \Delta_j - \Delta_j \Delta_i) P = 0,$$

will be identically satisfied. Hence Jacobi's method for the treatment of systems of this kind may be applied.

That the system is of the kind asserted is a consequence of the following proposition.

PROPOSITION. If the equations

$$[uP] = 0, \quad [vP] = 0$$

are expressed in the symbolic form

$$\Delta P = 0, \quad \Delta' P = 0,$$

then the derived equation

$$(\Delta \Delta' - \Delta' \Delta) P = 0 \dots\dots\dots (3),$$

will be equivalent to

$$[uv] P = 0.$$

For

$$\Delta = \sum_{i=1}^{i=n} \left( \frac{du}{dx_i} \frac{d}{dp_i} - \frac{du}{dp_i} \frac{d}{dx_i} \right),$$

$$\Delta' = \sum_{i=1}^{i=n} \left( \frac{dv}{dx_i} \frac{d}{dp_i} - \frac{dv}{dp_i} \frac{d}{dx_i} \right).$$

Hence since  $\frac{dv}{dx_j}$  is the coefficient of  $\frac{dP}{dp_j}$  in  $\Delta'P$ , and  $\frac{du}{dx_j}$  its coefficient in  $\Delta P$ , its coefficient in the derived equation (3) will be (Chap. xxv. Art. 5),

$$\Delta \frac{dv}{dx_j} - \Delta' \frac{du}{dx_j};$$

$$\text{or } \sum_{i=1}^{i=n} \left( \frac{du}{dx_i} \frac{d^2v}{dp_i dx_j} - \frac{du}{dp_i} \frac{d^2v}{dx_i dx_j} - \frac{dv}{dx_i} \frac{d^2u}{dp_i dx_j} + \frac{dv}{dp_i} \frac{d^2u}{dx_i dx_j} \right),$$

$$\text{or } \frac{d}{dx_j} \sum_{i=1}^{i=n} \left( \frac{du}{dx_i} \frac{dv}{dp_i} - \frac{du}{dp_i} \frac{dv}{dx_i} \right),$$

$$\text{or } \frac{d}{dx_j} [uv].$$

In like manner the coefficient of  $\frac{dP}{dx_j}$  is

$$- \frac{d}{dp_j} [uv].$$

$$\begin{aligned} \text{Hence } (\Delta\Delta' - \Delta'\Delta) P &= \sum_{j=1}^{j=n} \left( \frac{d[uv]}{dx_j} \frac{dP}{dp_j} - \frac{d[uv]}{dp_j} \frac{dP}{dx_j} \right) \\ &= \left[ [uv] P \right], \end{aligned}$$

whence the Proposition is established.

Applying this to the system (2) we see that any derived equation will be of the form

$$\left[ [F_i F_j] P \right] = 0.$$

But  $[F_i F_j] = 0$  by the conditions given; hence the condition  $(\Delta_i \Delta_j - \Delta_j \Delta_i) P = 0$ , is identically satisfied.

The results of Chapter xxvi. being thus directly applicable to the system under consideration, we see that a common integral of the system (2) may be found by a series of alter-

nate processes of integration and derivation. We begin by seeking an integral of the first partial differential equation. By a process of derivation, always possible, followed by the integration of a differential equation between two variables, we arrive at a common integral of the first two partial differential equations. Again, by a process of derivation followed by the solution of a differential equation we obtain a common integral of the first three partial differential equations. And so on, until a common integral of all is obtained.

7. Another solution of the above problem has recently been given. Beginning as in Jacobi's method by finding an integral of the first partial differential equation, a process of derivation agreeing in principle with Jacobi's, only more extended, *may* lead us without further integration to a point at which the discovery of a common integral of the entire system will depend only upon the solution of a single differential equation of the first order susceptible of being made integrable by a factor. Failing this, it will enable us to convert the given system of partial differential equations into a new system possessing the same general character, but containing one equation less. Upon this the same process may be tried with a similar final alternative—and so on till the required integral is discovered. (*On the Differential Equations of Dynamics. Philosophical Transactions*, 1863).

## CHAPTER XXVIII.

### PARTIAL DIFFERENTIAL EQUATIONS OF THE SECOND ORDER.

[THIS Chapter is a reconstruction on a larger scale of part of Chapter xv. At the end of the Chapter reference will be given to other writings of Professor Boole on the subject here discussed.]

1. The general form of a partial differential equation of the second order is

$$F(x, y, z, p, q, r, s, t) = 0 \dots\dots\dots(1),$$

where

$$p = \frac{dz}{dx}, \quad q = \frac{dz}{dy}, \quad r = \frac{d^2z}{dx^2}, \quad s = \frac{d^2z}{dx dy}, \quad t = \frac{d^2z}{dy^2}.$$

It is only in particular cases that the equation admits of integration, and the most important is that in which the differential coefficients of the second order present themselves only in the first degree; the equation thus assuming the form

$$Rr + Ss + Tt = V \dots\dots\dots(2),$$

in which  $R$ ,  $S$ ,  $T$ , and  $V$  are functions of  $x$ ,  $y$ ,  $z$ ,  $p$  and  $q$ .

The most important part of the theory of the solution of this equation is due to Monge, and was extended by Ampère to the more general equation

$$Rr + Ss + Tt + U(s^2 - rt) = V \dots\dots\dots(3).$$

This equation, together with the particular equation of Monge, and the equation

$$Rr + Ss + Tt + U(s^2 - rt) = 0,$$

both which though falling under Ampère's general form possess peculiarities demanding special notice, I propose to consider in this Chapter. I shall in conclusion make some observations on the theory of partial differential equations of the second order with more than two independent variables.

Monge's method, and Ampère's in so far as it is an extension of Monge's, consists in a certain procedure for discovering either one or two first integrals of the form

$$u = f(v) \dots\dots\dots (4),$$

$u$  and  $v$  being determinate functions of  $x, y, z, p$ , and  $q$ ; and  $f$  being an arbitrary functional symbol. From these first integrals, singly or in combination, the second integral involving two arbitrary functions is obtained by a subsequent integration.

Now this procedure involves the assumption that the proposed equation admits of a first integral of the form (4). But such is not always the case. There exist primitive equations involving two arbitrary functions, from which by proceeding to a second differentiation both functions may be eliminated and an equation of the form (2) obtained, but from which it is impossible to eliminate one function only so as to lead to an intermediate equation of the form (4). Especially this happens if the primitive involve an arbitrary function and its derived function together. Thus the primitive

$$z = \phi(y + x) + \psi(y - x) - x \{ \phi'(y + x) - \psi'(y - x) \} \dots (5),$$

leads to the partial differential equation of the second order

$$r - t = \frac{2p}{x} \dots\dots\dots (6),$$

but not through an intermediate equation of the form (4).

It is necessary therefore, not only to consider the case in which the assumed condition is satisfied, but also to notice

what has been done in those cases which do not at present fall under the dominion of any known method.

*Genesis of the Equation.*

2. PROP. I. *A partial differential equation of the first order of the form  $u = f(v)$ , or its symmetrical equivalent,*

$$F(u, v) = 0,$$

*in which  $u$  and  $v$  are any functions of  $x, y, z, p, q$ , always leads to a partial differential equation of the form*

$$Rr + Ss + Tt + U(s^2 - rt) = V.$$

For, differentiating the proposed first integral with respect to  $x$ , and with respect to  $y$ , we have

$$\begin{aligned} \frac{dF}{du} \left( \frac{du}{dx} + \frac{du}{dz} p + \frac{du}{dp} r + \frac{du}{dq} s \right) \\ + \frac{dF}{dv} \left( \frac{dv}{dx} + \frac{dv}{dz} p + \frac{dv}{dp} r + \frac{dv}{dq} s \right) &= 0, \\ \frac{dF}{du} \left( \frac{du}{dy} + \frac{du}{dz} q + \frac{du}{dp} s + \frac{du}{dq} t \right) \\ + \frac{dF}{dv} \left( \frac{dv}{dy} + \frac{dv}{dz} q + \frac{dv}{dp} s + \frac{dv}{dq} t \right) &= 0. \end{aligned}$$

For brevity, write

$$\left( \frac{du}{dx} \right) \text{ for } \frac{du}{dx} + p \frac{du}{dz}, \text{ and } \left( \frac{du}{dy} \right) \text{ for } \frac{du}{dy} + q \frac{du}{dz},$$

and then eliminating

$$\frac{dF}{du}, \quad \frac{dF}{dv},$$

we have

$$\begin{aligned} & \left\{ \left( \frac{du}{dx} \right) + \frac{du}{dp} r + \frac{du}{dq} s \right\} \left\{ \left( \frac{dv}{dy} \right) + \frac{dv}{dp} s + \frac{dv}{dq} t \right\} \\ &= \left\{ \left( \frac{du}{dy} \right) + \frac{du}{dp} s + \frac{du}{dq} t \right\} \left\{ \left( \frac{dv}{dx} \right) + \frac{dv}{dp} r + \frac{dv}{dq} s \right\}, \end{aligned}$$

which, on effecting the multiplication, gives

$$\begin{aligned} & \left\{ \frac{du}{dp} \left( \frac{dv}{dy} \right) - \left( \frac{du}{dy} \right) \frac{dv}{dp} \right\} r \\ &+ \left\{ \left( \frac{du}{dx} \right) \frac{dv}{dp} - \frac{du}{dp} \left( \frac{dv}{dx} \right) - \left( \frac{du}{dy} \right) \frac{dv}{dq} + \frac{du}{dq} \left( \frac{dv}{dy} \right) \right\} s \\ &+ \left\{ \left( \frac{du}{dx} \right) \frac{dv}{dq} - \frac{du}{dq} \left( \frac{dv}{dx} \right) \right\} t \\ &+ \left( \frac{du}{dq} \frac{dv}{dp} - \frac{du}{dp} \frac{dv}{dq} \right) (s^2 - rt) \\ &= \left( \frac{du}{dy} \right) \left( \frac{dv}{dx} \right) - \left( \frac{du}{dx} \right) \left( \frac{dv}{dy} \right) \dots\dots\dots (7), \end{aligned}$$

a result which, since  $u$  and  $v$  are by hypothesis given functions of  $x, y, z, p, q$ , is seen to be a particular case of the general form (3).

We may hence deduce also the conditions under which particular forms included in the general form (3) arise. Thus, in order that the equation  $u=f(v)$  may give rise to a partial differential equation of the second order of Monge's form

$$Rr + Ss + Tt = V,$$

it is necessary that the condition

$$\frac{du}{dq} \frac{dv}{dp} - \frac{du}{dp} \frac{dv}{dq} = 0$$

should be identically satisfied. This requires, by Chap. II.

Art. 1, that  $u$  and  $v$ , considered as functions of  $p$  and  $q$ , should not be independent.

3. The geometrical relations of the equation (3) are also remarkable. It may in particular be shewn that an equation of this form will be satisfied by the equation of any surface which constitutes the envelope of any system of surfaces formed by the variation of three parameters in subjection to two arbitrary conditions. For let the common equation of the enveloped surfaces be

$$z = f(x, y, a, b, c) \dots\dots\dots (8),$$

the parameters  $a, b, c$  varying in subjection to the conditions

$$\phi_1(a, b, c) = 0, \quad \phi_2(a, b, c) = 0,$$

conditions which, determining  $b$  and  $c$  as functions of  $a$ , may be reduced to the form

$$b = \phi(a), \quad c = \psi(a) \dots\dots\dots (9).$$

Now the values of  $p$  and  $q$  being the same for any point in the envelope as for the same point in the generating surface, we have for all such points

$$p = \frac{df(x, y, a, b, c)}{dx}, \quad q = \frac{df(x, y, a, b, c)}{dy} \dots\dots\dots (10).$$

These two equations in conjunction with (9) enable us to determine  $a, b, c$  as functions of  $x, y, z, p, q$ . Let these values be

$$a = u, \quad b = v, \quad c = w.$$

Then substituting in (9) we have

$$v = \phi(u), \quad w = \psi(u),$$

equations which hold for *all* such points. These are then the partial differential equations of the first order of the envelope.

Now each of these equations is of the general form (4); whence by Prop. 1. the partial differential equation of the second order is of the form (3), as was to be proved.

Let us actually construct this equation.

Differentiating the first of the equations (10) with respect to  $x$  and to  $y$ , and regarding therein  $a$  as a function of those variables, and  $b$  and  $c$  as functions of  $a$ , we have

$$r = \frac{d^2f}{dx^2} + \left( \frac{d^2f}{dadx} + \frac{d^2f}{dbdx} \frac{db}{da} + \frac{d^2f}{dcdx} \frac{dc}{da} \right) \frac{da}{dx},$$

$$s = \frac{d^2f}{dxdy} + \left( \frac{d^2f}{dadx} + \frac{d^2f}{dbdx} \frac{db}{da} + \frac{d^2f}{dcdx} \frac{dc}{da} \right) \frac{da}{dy},$$

from which we readily derive

$$\left( r - \frac{d^2f}{dx^2} \right) \frac{da}{dy} - \left( s - \frac{d^2f}{dxdy} \right) \frac{da}{dx} = 0.$$

Proceeding in the same way with the second equation of the system (10) we have

$$\left( s - \frac{d^2f}{dxdy} \right) \frac{da}{dy} - \left( t - \frac{d^2f}{dy^2} \right) \frac{da}{dx} = 0.$$

Hence, eliminating  $\frac{da}{dx}$  and  $\frac{da}{dy}$ , we have

$$\left( s - \frac{d^2f}{dxdy} \right)^2 - \left( r - \frac{d^2f}{dx^2} \right) \left( t - \frac{d^2f}{dy^2} \right) = 0$$

or  $\frac{d^2f}{dy^2} r - 2 \frac{d^2f}{dxdy} s + \frac{d^2f}{dx^2} t + s^2 - rt = \frac{d^2f}{dx^2} \frac{d^2f}{dy^2} - \left( \frac{d^2f}{dxdy} \right)^2,$

the equation sought.

Comparing this with the general form (3) we have the equations

$$\frac{\frac{d^2f}{dy^2}}{R} = \frac{-2 \frac{d^2f}{dxdy}}{S} = \frac{\frac{d^2f}{dx^2}}{T} = \frac{1}{U} = \frac{\frac{d^2f}{dx^2} \frac{d^2f}{dy^2} - \left( \frac{d^2f}{dxdy} \right)^2}{V},$$

whence eliminating  $\frac{d^2f}{dx^2}$ ,  $\frac{d^2f}{dy^2}$ , and  $\frac{d^2f}{dxdy}$  we arrive at the equation,

$$S^2 + 4(UV - RT) = 0.$$

This then is the condition which must be satisfied in order that the equation (3) may admit of an integral representing the envelope of a system of surfaces in which three parameters vary in subjection to two connecting conditions. It is only proved however to be a *necessary*, not to be a *sufficient*, condition.

*Solution of the equation  $Rr + Ss + Tt + U(s^2 - rt) = V$ , when a first integral of the form  $F(u, v) = 0$ , exists.*

4. In the following sections we propose

1st. To shew that when a first integral of the above form exists, its discovery depends upon the solution of two simultaneous partial differential equations of the first order resolvable into linear equations.

2ndly. To shew how from such first integral or integrals the second integral is to be obtained.

PROP. II. *If the equation*

$$Rr + Ss + Tt + U(s^2 - rt) = V$$

*admit of a first integral of the form  $F(u, v) = 0$ , in which  $u$  and  $v$  are functions of  $x, y, z, p, q$ , then will  $F(u, v)$  considered as a function of  $x, y, z, p, q$ , and represented as such for brevity by  $F$  satisfy the two partial differential equations of the first order,*

$$\begin{aligned} R \left( \frac{dF}{dx} \right) \frac{dF}{dq} + T \left( \frac{dF}{dy} \right) \frac{dF}{dp} + U \left( \frac{dF}{dx} \right) \left( \frac{dF}{dy} \right) \\ + V \frac{dF}{dp} \frac{dF}{dq} = 0, \end{aligned}$$

$$R \left( \frac{dF}{dq} \right)^2 - S \frac{dF}{dq} \frac{dF}{dp} + T \left( \frac{dF}{dp} \right)^2 \\ + U \left\{ \left( \frac{dF}{dx} \right) \frac{dF}{dp} + \left( \frac{dF}{dy} \right) \frac{dF}{dq} \right\} = 0,$$

in which

$$\left( \frac{dF}{dx} \right) = \frac{dF}{dx} + p \frac{dF}{dz}, \quad \left( \frac{dF}{dy} \right) = \frac{dF}{dy} + q \frac{dF}{dz}.$$

Regarding the function  $F$  in the proposed integral  $F=0$  simply as a function of  $x, y, z, p, q$ , we have

$$\left. \begin{aligned} \left( \frac{dF}{dx} \right) + \frac{dF}{dp} r + \frac{dF}{dq} s &= 0 \\ \left( \frac{dF}{dy} \right) + \frac{dF}{dp} s + \frac{dF}{dq} t &= 0 \end{aligned} \right\} \dots\dots\dots (11).$$

On the other hand, regarding  $F$  as a function of  $x, y, z, p, q$ , mediately through  $u$  and  $v$ , we have the system

$$\left. \begin{aligned} \frac{dF}{du} \left\{ \left( \frac{du}{dx} \right) + \frac{du}{dp} r + \frac{du}{dq} s \right\} + \frac{dF}{dv} \left\{ \left( \frac{dv}{dx} \right) + \frac{dv}{dp} r + \frac{dv}{dq} s \right\} &= 0, \\ \frac{dF}{du} \left\{ \left( \frac{du}{dy} \right) + \frac{du}{dp} s + \frac{du}{dq} t \right\} + \frac{dF}{dv} \left\{ \left( \frac{dv}{dy} \right) + \frac{dv}{dp} s + \frac{dv}{dq} t \right\} &= 0, \end{aligned} \right\} (12),$$

and these systems are *equivalent*.

Now if from the second of these systems we eliminate  $\frac{dF}{du}$  and  $\frac{dF}{dv}$ , we obtain (Art. 2), a result which must be equivalent to the proposed partial differential equation,

$$Rr + Ss + Tt + U(s^2 - rt) = V \dots\dots\dots (13).$$

This equation then considered as a relation between  $r, s, t$ , must be an algebraical consequence of the relations (12), and

therefore of the equations (11). If then we determine algebraically two of the quantities  $r, s, t$ , (we select  $r, t$ ) from the system, and substitute their values in (13), that equation ought to be satisfied independently of the value of the remaining quantity  $s$ . Now supposing  $p$  and  $q$  to be both contained in  $F$ , so that neither  $\frac{dF}{dp}$  nor  $\frac{dF}{dq}$  vanish, we have from (11),

$$r = - \frac{\left(\frac{dF}{dx}\right) + \frac{dF}{dq} s}{\frac{dF}{dp}}, \quad t = - \frac{\left(\frac{dF}{dy}\right) + \frac{dF}{dp} s}{\frac{dF}{dq}},$$

substituting which in (13) there results

$$\begin{aligned} & R \left(\frac{dF}{dx}\right) \frac{dF}{dq} + T \left(\frac{dF}{dy}\right) \frac{dF}{dp} + U \left(\frac{dF}{dx}\right) \left(\frac{dF}{dy}\right) + V \frac{dF}{dp} \frac{dF}{dq} \\ & + \left\{ R \left(\frac{dF}{dq}\right)^2 - S \frac{dF}{dq} \frac{dF}{dp} + T \left(\frac{dF}{dp}\right)^2 \right. \\ & \quad \left. + U \left(\frac{dF}{dx}\right) \frac{dF}{dp} + U \left(\frac{dF}{dy}\right) \frac{dF}{dq} \right\} s = 0 \dots (14). \end{aligned}$$

Now as this equation is to be satisfied in virtue of the constitution of  $R, S, T, U, V$ , and the function  $F$ , and independently of  $s$ , both the coefficient of  $s$  and the absolute term not containing  $s$  must be separately equated to 0. Thus  $F$  considered as a function of  $x, y, z, p, q$ , and containing  $p, q$ , at least must satisfy the partial differential equations

$$\left. \begin{aligned} & R \left(\frac{dF}{dx}\right) \frac{dF}{dq} + T \left(\frac{dF}{dy}\right) \frac{dF}{dp} \\ & \quad + U \left(\frac{dF}{dx}\right) \left(\frac{dF}{dy}\right) + V \frac{dF}{dp} \frac{dF}{dq} = 0 \\ & R \left(\frac{dF}{dq}\right)^2 - S \frac{dF}{dp} \frac{dF}{dq} + T \left(\frac{dF}{dp}\right)^2 \\ & \quad + U \left\{ \left(\frac{dF}{dx}\right) \frac{dF}{dp} + \left(\frac{dF}{dy}\right) \frac{dF}{dq} \right\} = 0 \end{aligned} \right\} \dots (15).$$

This result may also be established by forming the equations of condition which express the proportionality of  $R, S, \dots V$ , to the corresponding quantities in the constructed equation (7). From these equations of condition it is actually possible to eliminate in two distinct ways the quantities  $\left(\frac{dv}{dx}\right), \left(\frac{dv}{dy}\right), \frac{dv}{dp}, \frac{dv}{dq}$ , the result being the formation of two partial differential equations for  $u$  agreeing in form with those above given for  $F$ . (See the memoir *Ueber die partielle Differentialgleichung...* *Crelle's Journal*, Vol. 61.) The actual transition from the former to the latter rests upon the consideration that the equation  $F(u, v) = 0$ , when  $F$  is arbitrary, is not really less general than the form  $\Phi\{F(u, v), v\} = 0$ , in which the  $\Phi$  is arbitrary. And here  $u$  has been replaced by  $F(u, v)$ .

The only condition respecting the application of the above equations is that we do not admit any relations which make either  $\frac{dF}{dp}$  or  $\frac{dF}{dq}$  to vanish.

5. PROP. III. *The solution of the system of partial differential equations established in the last proposition may in all cases be made to depend upon that of simultaneous linear partial differential equations of the first order.*

In demonstrating this proposition we shall consider first the case in which  $U=0$ , then the case in which  $V=0$ , lastly the case in which neither of these quantities vanishes. The ground of this division will appear in the investigation.

Case 1. Suppose  $U=0$ . The equation then is of Monge's form,

$$Rr + Ss + Tt = V.$$

The second equation of the system (15) becomes

$$R\left(\frac{dF}{dq}\right)^2 - S\frac{dF}{dp}\frac{dF}{dq} + T\left(\frac{dF}{dp}\right)^2 = 0,$$

and therefore breaks up into the equations

$$\frac{dF}{dq} - m_1 \frac{dF}{dp} = 0, \quad \frac{dF}{dq} - m_2 \frac{dF}{dp} = 0,$$

$m_1$  and  $m_2$  being the roots of the quadratic equation

$$Rm^2 - Sm + T = 0 \dots\dots\dots(16).$$

As each of the above constituent equations is of the form

$$\frac{dF}{dq} = m \frac{dF}{dp},$$

the system (15) may be reduced to the form

$$Rm \left( \frac{dF}{dx} \right) \frac{dF'}{dp} + T \left( \frac{dF'}{dy} \right) \frac{dF}{dp} + Vm \frac{dF}{dp} \frac{dF'}{dp} = 0,$$

which breaks up into the equations

$$\frac{dF}{dp} = 0, \quad Rm \left( \frac{dF'}{dx} \right) + T \left( \frac{dF'}{dy} \right) + Vm \frac{dF'}{dp} = 0.$$

The former of these we must reject (Art. 4). There remains for the determination of  $F'$  the system of *linear* partial differential equations

$$\left. \begin{aligned} \frac{dF'}{dq} - m \frac{dF'}{dp} &= 0 \\ Rm \left( \frac{dF'}{dx} \right) + T \left( \frac{dF'}{dy} \right) + Vm \frac{dF'}{dp} &= 0 \end{aligned} \right\} \dots\dots\dots(17),$$

and there will exist either one or two systems included under this form, according as the roots of the quadratic (16) are equal or unequal.

*Case II.* Let  $V = 0$ . The system (15) then becomes

$$R \left( \frac{dF}{dx} \right) \frac{dF}{dq} + T \left( \frac{dF}{dy} \right) \frac{dF}{dp} + U \left( \frac{dF}{dx} \right) \left( \frac{dF}{dy} \right) = 0,$$

$$R \left( \frac{dF}{dq} \right)^2 - S \frac{dF}{dq} \frac{dF}{dp} + T \left( \frac{dF}{dp} \right)^2$$

$$+ U \left\{ \left( \frac{dF}{dx} \right) \frac{dF}{dp} + \left( \frac{dF}{dy} \right) \frac{dF}{dq} \right\} = 0.$$

Eliminate  $U$  by multiplying the first equation by

$$\left( \frac{dF}{dx} \right) \frac{dF}{dp} + \left( \frac{dF}{dy} \right) \frac{dF}{dq},$$

the second by

$$\left( \frac{dF}{dx} \right) \left( \frac{dF}{dy} \right),$$

and subtracting; we obtain, after rejection of the common factor  $\frac{dF}{dp} \frac{dF}{dq}$ ,

$$R \left( \frac{dF}{dx} \right)^2 + S \left( \frac{dF}{dx} \right) \left( \frac{dF}{dy} \right) + T \left( \frac{dF}{dy} \right)^2 = 0.$$

We shall put this equation in the place of the second equation of the system. This we are permitted to do under the restriction that in seeking to satisfy the system so changed we do not make use of any relations which would cause either of the two factors employed in the process of elimination to vanish or become infinite.

The new equation reduces to one equation, or breaks up into two equations of the form

$$\left( \frac{dF}{dx} \right) - m \left( \frac{dF}{dy} \right) = 0 \dots\dots\dots (18),$$

$m$  being determined by the quadratic equation

$$Rm^2 + Sm + T = 0.$$

Making  $\left(\frac{dF'}{dx}\right) = m \left(\frac{dF'}{dy}\right)$  in the first equation of the system (15), we get

$$\left(\frac{dF'}{dy}\right) \left\{ Rm \frac{dF'}{dq} + T \frac{dF'}{dp} + Um \left(\frac{dF'}{dy}\right) \right\} = 0,$$

which breaks up into

$$\left(\frac{dF'}{dy}\right) = 0, \quad Rm \frac{dF'}{dq} + T \frac{dF'}{dp} + Um \left(\frac{dF'}{dy}\right) = 0.$$

But if we combine the first of these with (18), we obtain

$$\left(\frac{dF'}{dy}\right) = 0, \quad \left(\frac{dF'}{dx}\right) = 0,$$

and this combination causing both the factors employed in the elimination of  $U$  to vanish must be rejected. There remains then the combination

$$\left. \begin{aligned} \left(\frac{dF'}{dx}\right) - m \left(\frac{dF'}{dy}\right) &= 0 \\ Rm \frac{dF'}{dq} + T \frac{dF'}{dp} + Um \left(\frac{dF'}{dy}\right) &= 0 \end{aligned} \right\} \dots\dots\dots (19),$$

and this will represent either one or two systems of equations according as the quadratic determining  $m$  has equal or unequal roots.

*Case III.* Let neither  $U=0$  nor  $V=0$ .

Multiply the second equation of the system (15) by an indeterminate quantity  $l$ , and add to the first; then we have

$$\begin{aligned} Rl \left(\frac{dF'}{dq}\right)^2 + Tl \left(\frac{dF'}{dp}\right)^2 + U \left(\frac{dF'}{dx}\right) \left(\frac{dF'}{dy}\right) \\ + Ul \left(\frac{dF'}{dx}\right) \frac{dF'}{dp} + T \left(\frac{dF'}{dy}\right) \frac{dF'}{dp} \\ + Ul \left(\frac{dF'}{dy}\right) \frac{dF'}{dq} + R \left(\frac{dF'}{dx}\right) \frac{dF'}{dq} \\ + (V - Sl) \frac{dF'}{dp} \frac{dF'}{dq} = 0 \dots\dots\dots (20). \end{aligned}$$

We shall enquire whether it is possible so to determine  $l$  as to resolve this into linear factors.

We might investigate this by resolving the equation as a quadratic with respect to  $\frac{dF}{dq}$  or  $\frac{dF}{dp}$ . But the form of the equation suggests what the forms of the linear factors must be if the resolution be possible. For as the squares of  $\frac{dF}{dq}$  and  $\frac{dF}{dp}$  both appear, and these squares alone, in the function to be resolved, it is clear that  $\frac{dF}{dq}$  and  $\frac{dF}{dp}$  will be the only differential coefficients of  $F$  which will appear in both linear factors in common. The most general supposition possible is then that one factor shall contain  $\frac{dF}{dq}$  and  $\frac{dF}{dp}$  with  $\left(\frac{dF}{dx}\right)$ , the other the same with  $\left(\frac{dF}{dy}\right)$ .

Assuming then one factor to be of the form

$$l \frac{dF}{dq} + m \frac{dF}{dp} + n \left(\frac{dF}{dx}\right),$$

it is seen from the form of the coefficients of the first three terms of (20) that the other factor must be of the form

$$R \frac{dF}{dq} + \frac{Tl}{m} \frac{dF}{dp} + \frac{U}{n} \left(\frac{dF}{dy}\right),$$

and the resolved form of (20) must be

$$\left\{ R \frac{dF}{dq} + \frac{Tl}{m} \frac{dF}{dp} + \frac{U}{n} \left(\frac{dF}{dy}\right) \right\} \left\{ l \frac{dF}{dq} + m \frac{dF}{dp} + n \left(\frac{dF}{dx}\right) \right\} = 0.$$

Multiplying out and equating coefficients, we obtain the conditions

$$Ul = \frac{Tln}{m},$$

$$T = \frac{Um}{n},$$

$$Ul = \frac{Ul}{n},$$

$$R = Rn,$$

$$V - Sl = Rm + \frac{Tl^2}{m}.$$

The third and fourth of these conditions are equivalent, and give  $n=1$ . The first and second are also equivalent, and give  $m = \frac{T}{U}$ . These values reduce the last equation of condition to

$$Ul^2 + Sl + \frac{RT}{U} - V = 0,$$

so that  $l$  is determined by a quadratic. The resolved form of equation (20) now becomes

$$\left\{ R \frac{dF}{dq} + Ul \frac{dF}{dp} + U \left( \frac{dF}{dy} \right) \right\} \left\{ l \frac{dF}{dq} + \frac{T}{U} \frac{dF}{dp} + \left( \frac{dF}{dx} \right) \right\} = 0.$$

To these results we may give a somewhat simpler form by making  $Ul=m$ ; not the  $m$  used above. We have then as the quadratic for determining  $m$ ,

$$m^2 + Sm + RT - UV = 0 \dots\dots\dots (21),$$

and as the resolved form of (20),

$$\left\{ R \frac{dF}{dq} + m \frac{dF}{dp} + U \left( \frac{dF}{dy} \right) \right\} \left\{ m \frac{dF}{dq} + T \frac{dF}{dp} + U \left( \frac{dF}{dx} \right) \right\} = 0.$$

Let  $m_1$  and  $m_2$  be the values of  $m$ . Then we have from the last the two distinct equations

$$\left\{ R \frac{dF}{dq} + m_1 \frac{dF}{dp} + U \left( \frac{dF}{dy} \right) \right\} \left\{ m_1 \frac{dF}{dq} + T \frac{dF}{dp} + U \left( \frac{dF}{dx} \right) \right\} = 0,$$

$$\left\{ R \frac{dF}{dq} + m_2 \frac{dF}{dp} + U \left( \frac{dF}{dy} \right) \right\} \left\{ m_2 \frac{dF}{dq} + T \frac{dF}{dp} + U \left( \frac{dF}{dx} \right) \right\} = 0,$$

and it is evident that these will be together equivalent to the equations (15) from which they were derived.

Now to satisfy these equations simultaneously it is necessary that we should equate to 0 one linear factor from each of their first members. If we equate to 0 the first linear factors, we have

$$R \frac{dF}{dq} + m_1 \frac{dF}{dp} + U \left( \frac{dF}{dy} \right) = 0,$$

$$R \frac{dF}{dq} + m_2 \frac{dF}{dp} + U \left( \frac{dF}{dy} \right) = 0;$$

whence, by subtraction,

$$(m_1 - m_2) \frac{dF}{dp} = 0.$$

This combination must therefore be rejected (Art. 4). For the same reason must the combination formed by equating to 0 the second linear factors in the left-hand members of the above two equations be rejected. There remains then only the combinations formed by equating to 0 the first factor of one of these members, and the second of the other.

Thus we should have the combination

$$\left. \begin{aligned} R \frac{dF}{dq} + m_1 \frac{dF}{dp} + U \left( \frac{dF}{dy} \right) &= 0 \\ m_2 \frac{dF}{dq} + T \frac{dF}{dp} + U \left( \frac{dF}{dx} \right) &= 0 \end{aligned} \right\} \dots\dots\dots (22),$$

with the combination which would be obtained from this by interchanging  $m_1$  and  $m_2$ .

6. It results from the foregoing investigations that the function  $F$  is in all cases to be determined by the solution of two simultaneous linear partial differential equations with *five* independent variables. Now the theory developed in Chapter XXV. shews that the number of integrals of such a system cannot exceed *three*. That theory enables us both to determine what the number of integrals is, and to construct the system of ordinary differential equations, reducible to the exact form, upon which their discovery depends.

We have seen that the knowledge of two integrals  $u = a$ ,  $v = b$  of the system enables us to construct a general first integral

$$F(u, v) = 0,$$

of the partial differential equation (3). And the solution of this first integral would lead us to the second integral which is the final object sought. But the direct solving of a partial differential equation of the first order which is not linear and which involves in its actual expression an arbitrary function is difficult, and happily it may be avoided here. The following propositions will enable us to accomplish the virtual solution by a different solution, founded however upon the same general principles.

7. PROP. IV. *The integrals of the respective systems of simultaneous linear partial differential equations upon which the determination of  $F$  depends are so related that if from two such respective integrals the values of  $p$  and  $q$  are determined, they will render the equation*

$$dz = p dx + q dy$$

*integrable. And in the particular case in which the two systems become identical, any two integrals of the system stand in the same relation.*

For, let  $\Phi$  be an integral of the system (22), and  $\Psi$  an integral of the associated system obtained by interchanging  $m_1$  and  $m_2$  in the case in which these quantities are different. Then  $\Phi$  satisfies the equations

$$R \frac{d\Phi}{dq} + m_1 \frac{d\Phi}{dp} + U \left( \frac{d\Phi}{dy} \right) = 0,$$

$$m_2 \frac{d\Phi}{dq} + T \frac{d\Phi}{dp} + U \left( \frac{d\Phi}{dx} \right) = 0;$$

and  $\Psi$  satisfies the equations

$$R \frac{d\Psi}{dq} + m_2 \frac{d\Psi}{dp} + U \left( \frac{d\Psi}{dy} \right) = 0,$$

$$m_1 \frac{d\Psi}{dq} + T \frac{d\Psi}{dp} + U \left( \frac{d\Psi}{dx} \right) = 0.$$

But the necessary and sufficient condition in order that the values of  $p$  and  $q$  derived from the equations  $\Phi = 0$ ,  $\Psi = 0$ , may render  $dz - p dx - q dy$  integrable, is

$$\left( \frac{d\Phi}{dx} \right) \frac{d\Psi}{dp} - \frac{d\Phi}{dp} \left( \frac{d\Psi}{dx} \right) \\ + \left( \frac{d\Phi}{dy} \right) \frac{d\Psi}{dq} - \frac{d\Phi}{dq} \left( \frac{d\Psi}{dy} \right) = 0 \dots\dots (23).$$

See Chap. XIV. Art. 11, Equation (36).

Now if from the previous equations we determine the values of

$$\left( \frac{d\Phi}{dx} \right), \quad \left( \frac{d\Phi}{dy} \right), \quad \left( \frac{d\Psi}{dx} \right), \quad \left( \frac{d\Psi}{dy} \right),$$

and substitute them in the above equation of condition it will be identically satisfied.

The determination of  $\left(\frac{d\Phi}{dx}\right), \dots$  from the previous systems requires that  $U$  should not vanish. Hence the proposition is established except in the case of  $U=0$ , which is left doubtful.

To examine this case let us revert to the system (17) which is proper to it. To that system since

$$Rm^2 - Sm + T = 0,$$

whence

$$Rm_1m_2 = T,$$

we may give the form

$$\frac{dF}{dq} - m_1 \frac{dF}{dp} = 0, \quad \left(\frac{dF}{dx}\right) + m_2 \left(\frac{dF}{dy}\right) + \frac{V}{R} \frac{dF}{dp} = 0,$$

or the form obtained from this by interchanging  $m_1$  and  $m_2$ .

Substituting in these respective forms  $\Phi$  and  $\Psi$  in succession for  $F$ , we find

$$\frac{d\Phi}{dq} = m_1 \frac{d\Phi}{dp}, \quad \left(\frac{d\Phi}{dx}\right) = -m_2 \left(\frac{d\Phi}{dy}\right) - \frac{V}{R} \frac{d\Phi}{dp},$$

$$\frac{d\Psi}{dq} = m_2 \frac{d\Psi}{dp}, \quad \left(\frac{d\Psi}{dx}\right) = -m_1 \left(\frac{d\Psi}{dy}\right) - \frac{V}{R} \frac{d\Psi}{dp},$$

and these values substituted in (23) reduce it to an identity. Thus the proposition is established generally.

Lastly, as in the case in which the two roots of the quadratic for determining  $m$  are equal, the two systems of partial differential equations for determining  $\Phi$  and  $\Psi$  become one, it follows that if from two integrals of that one system we can deduce values of  $p$  and  $q$  these values will render the equation

$$dz - pdx - qdy = 0$$

integrable.

8. PROP. V. *When the system of simultaneous linear partial differential equations determining  $F$  admits of two integrals  $u = a$ ,  $v = b$ , it will admit or will not admit of a third integral  $w = c$ , according as the roots of the quadratic determining  $m$  are equal or unequal.*

The system in question, (22), becomes when we divide by  $U$  and write for  $\left(\frac{dF}{dy}\right)$  and  $\left(\frac{dF}{dx}\right)$  their full expressions

$$\frac{dF}{dy} + q \frac{dF}{dz} + \frac{m_1}{U} \frac{dF}{dp} + \frac{R}{U} \frac{dF}{dq} = 0,$$

$$\frac{dF}{dx} + p \frac{dF}{dz} + \frac{T}{U} \frac{dF}{dp} + \frac{m_2}{U} \frac{dF}{dq} = 0,$$

$$\text{or } \Delta_1 F = 0, \quad \Delta_2 F = 0,$$

in which

$$\Delta_1 = \frac{d}{dy} + q \frac{d}{dz} + \frac{m_1}{U} \frac{d}{dp} + \frac{R}{U} \frac{d}{dq},$$

$$\Delta_2 = \frac{d}{dx} + p \frac{d}{dz} + \frac{T}{U} \frac{d}{dp} + \frac{m_2}{U} \frac{d}{dq}.$$

Hence the equation

$$(\Delta_1 \Delta_2 - \Delta_2 \Delta_1) F = 0$$

becomes

$$\frac{m_1 - m_2}{U} \frac{dF}{dz} + \left( \Delta_1 \frac{T}{U} - \Delta_2 \frac{m_1}{U} \right) \frac{dF}{dp} + \left( \Delta_1 \frac{m_2}{U} - \Delta_2 \frac{R}{U} \right) \frac{dF}{dq} = 0.$$

In this expression the coefficient of the first term only has been calculated.

Now, by the theory developed in Chap. xxv. in order that the two simultaneous partial differential equations should have their full complement of integrals (three) it is necessary that the above equation should be satisfied identically. This involves three conditions, namely,

$$m_1 - m_2 = 0,$$

$$\Delta_1 \frac{T}{U} - \Delta_2 \frac{m_1}{U} = 0,$$

$$\Delta_1 \frac{m_2}{U} - \Delta_2 \frac{R}{U} = 0,$$

the first of which is the one affirmed in the Proposition to be necessary.

Secondly, it is to be shewn that if this condition be satisfied and if the system of given linear equations admit of two integrals  $u = a$ ,  $v = b$ , it will admit of a third.

Replacing  $m_1$  and  $m_2$  by  $m$  the system becomes

$$\frac{dF}{dy} + q \frac{dF}{dz} + \frac{m}{U} \frac{dF}{dp} + \frac{R}{U} \frac{dF}{dq} = 0,$$

$$\frac{dF}{dx} + p \frac{dF}{dz} + \frac{T}{U} \frac{dF}{dp} + \frac{m}{U} \frac{dF}{dq} = 0.$$

Now if we construct from this the corresponding system of *ordinary* differential equations, we shall find it to be

$$dz - p dx - q dy = 0,$$

$$dp - \frac{T}{U} dx - \frac{m}{U} dy = 0,$$

$$dq - \frac{m}{U} dx - \frac{R}{U} dy = 0.$$

Now it is impossible that the first of these equations should be integrated without a previous determination of  $p$  and  $q$  as functions of  $x$ ,  $y$ ,  $z$ , seeing that  $dx$ ,  $dy$ ,  $dz$  are the three differentials entering into that equation. Such determination can only come from the integration of the second and third equations of the system. But if these equations can be integrated in the forms  $u = a$ ,  $v = b$ , then  $u$  and  $v$  being particular values of  $F$  satisfying the partial differential equations, it follows from the last Proposition that the values of  $p$  and  $q$  which they will yield will make the first equation integrable. Hence if the system admits of two integrals it will admit of three; as was to be shewn. On the basis of these Propositions the theory of the second integration rests.

*Theory of the Second Integration.*

9. First suppose the values of  $m$  unequal.

Then  $u_1 = a_1$ ,  $v_1 = b_1$  being the two integrals (and we have seen that there cannot be more than two) of one of the systems of linear partial differential equations, and  $u_2 = a_2$ ,  $v_2 = b_2$  those of the other, the general first integrals of the given system will be

$$\Phi(u_1, v_1) = 0, \quad \Psi(u_2, v_2) = 0.$$

The values of  $p$  and  $q$  determined from these will by Proposition IV. render

$$dz - p dx - q dy = 0$$

integrable, and the integral of this will be the *general* integral of the proposed partial differential equation. For it will involve explicitly or implicitly two arbitrary functions derived from those in the first integrals.

It suffices however, following herein Charpit's method, to combine one general first integral derived from the one system with a particular first integral derived from the other system, e.g. the integrals

$$\Phi(u_1, v_1) = 0, \quad u_2 = a.$$

The values of  $p$  and  $q$  hence derived, and employed as before, will lead to a second integral involving one arbitrary function and containing two arbitrary constants. This constitutes a complete primitive from which the general solution will be obtained by converting one of the arbitrary constants into an arbitrary function of the other, and eliminating the latter between the equation and the one derived from it by differentiation with respect to that constant.

Secondly, suppose the values of  $m$  equal.

In this case we have but one system of partial differential equations so constituted however that if it admits of two integrals it will admit of three.

Let  $u = a$ ,  $v = b$ ,  $w = c$  represent these integrals. Then if from these we eliminate  $p$  and  $q$  we shall obtain a final integral of the form

$$z = f(x, y, a, b, c),$$

and this constitutes a complete primitive from which we shall deduce the general integral by making  $b = \phi(a)$ ,  $c = \psi(a)$ , and eliminating  $a$  between the equations

$$\begin{aligned} z &= f\{x, y, a, \phi(a), \psi(a)\} \\ 0 &= \frac{df\{x, y, a, \phi(a), \psi(a)\}}{da}. \end{aligned}$$

To prove this let us combine the general and particular first integrals

$$v = \phi(u), \quad u = a.$$

The values of  $p$  and  $q$  hence obtained make

$$dz - p dx - q dy = 0$$

integrable, and the result can be no other than the remaining integral  $w = c$ , or rather what this would become on eliminating  $p$  and  $q$  from it. But since the equations by which this integration are to be effected are equivalent to

$$u = a, \quad v = \phi(a),$$

$w$  will become a function of  $x, y, z, a$  and  $\phi(a)$ . Also by Charpit's method  $c$  is to be treated as a function of  $a$ , so that ultimately we have the result above assigned.

We have here supposed  $U$  not to vanish. If it do the theory assumes another but simpler form. Let

$$v = f(u), \quad w = \psi(u)$$

be the two general first integrals. Then, since by the condition at the close of Art. 2, if  $p$  be eliminated from these equations  $q$  will also disappear, it suffices to eliminate them together in order to obtain the general second integral.

10. Although the cases in which  $U=0$  and  $V=0$  have in the foregoing sections been treated for simplicity apart, their theory might have been deduced from that of the case in which neither  $U$  nor  $V$  vanishes.

Thus to deduce the equations for the case of  $U=0$  eliminate from the general system (22)  $\frac{dF}{dq}$  and  $\frac{dF}{dp}$  in succession, and we find

$$(RT - m_1 m_2) \frac{dF}{dp} - Um_2 \left( \frac{dF}{dy} \right) + UR \left( \frac{dF}{dx} \right) = 0,$$

$$(RT - m_1 m_2) \frac{dF}{dq} + UT \left( \frac{dF}{dy} \right) - Um_1 \left( \frac{dF}{dx} \right) = 0.$$

But from (21)  $RT - m_1 m_2 = UV$ .

Substituting, and then dividing by  $U$  we find

$$V \frac{dF}{dp} - m_2 \left( \frac{dF}{dy} \right) + R \left( \frac{dF}{dx} \right) = 0,$$

$$V \frac{dF}{dq} + T \left( \frac{dF}{dy} \right) - m_1 \left( \frac{dF}{dx} \right) = 0,$$

the equation determining  $m_1, m_2$  being

$$m^2 + Sm + RT = 0.$$

This is equivalent to the results of Art. 5, Case 1.

11. We found it necessary (Art. 3) in order that the general partial differential equation of this Chapter should be satisfied by the envelope of a system of surfaces the equations of which contain three parameters varying under two conditions that the relation

$$S^2 + 4(UV - RT) = 0$$

should be satisfied.

It appears from Art. 8 that this is but one of three conditions necessary and together sufficient for this purpose. The formal conditions for every form of ultimate solution consistent with the existence of a general first integral  $F(u, v) = 0$  can be deduced in the same way.

[In the *Bulletin de l'Académie Impériale des Sciences de St Pétersbourg*, Vol. IV. 1862, there is an article entitled *Considérations sur la recherche des intégrales premières des équations différentielles partielles du second ordre*, par G. Boldt (Lu le 7 Juin 1861).

The article occupies pages 198—215 of the volume. Although the name does not quite correspond, I consider that to be a misprint, and I attribute the article to Professor Boole, partly from the nature of the contents, and partly because it is known by his friends that he was engaged at a time corresponding to the date here given in the preparation of a mathematical article in French.

The object of the article is to determine the conditions necessary for the existence of a first integral of the equation

$$R \frac{d^2 z}{dx^2} + S \frac{d^2 z}{dxdy} + T \frac{d^2 z}{dy^2} + W = 0,$$

where  $R$ ,  $S$ ,  $T$ , and  $W$  are any functions of  $x$ ,  $y$ ,  $z$ ,  $\frac{dz}{dx}$  and  $\frac{dz}{dy}$ ; and also to determine the conditions which must hold in order that Ampère's method of integration may be employed.

In Crelle's Journal, Vol. LXI. there is an article by Professor Boole, entitled *Ueber die partielle Differentialgleichung zweiter Ordnung*  $Rr + Ss + Tt + U(s^2 - rt) = V$ .

The article is dated 1862; it occupies pages 309—333 of the volume.

Among Professor Boole's manuscripts I found a memoir very closely resembling the article in Crelle's Journal; it

would appear that the memoir was drawn up with a view to publication in the Transactions of some English Scientific Society, and that this design was afterwards abandoned in favour of the article in Crelle's Journal.

After some hesitation I have resolved to print this memoir. Even if the memoir had been identical with the article in Crelle's Journal it would have been convenient to the English reader to be able to avail himself of the investigations; and the memoir contains remarks which do not occur in the article, and which are interesting in connexion with the history of the subject. There is some repetition of matter which has already been given in Chapter XXVIII.; but I was unwilling to impair the completeness of the memoir by abridgment or omission. Accordingly the memoir forms the next Chapter of the present volume.

In Article 2 of the next Chapter will be found the process to which there is an allusion towards the end of Article 4 of Chapter XXVIII.

It is obvious that the subject of partial differential equations of the second order was much studied by Professor Boole. The chronological order of his writings on the subject appears to be as follows :

1. Chapter xv. of the first edition of his work.
2. The article in the *Bulletin* of St Petersburg.
3. The memoir which forms Chapter XXIX. of the present volume.
4. The article in Crelle's Journal.
5. The Chapter XXVIII. of the present volume.]

## CHAPTER XXIX.

ON THE SOLUTION OF THE PARTIAL DIFFERENTIAL EQUATION  
 $Rr + Ss + Tt + U(s^2 - rt) = V$ , IN WHICH  $R, S, T, U, V$   
 ARE GIVEN FUNCTIONS OF  $x, y, z, p, q$ .

1. THE equation, the theory of the solution of which I propose to consider in this paper, is remarkable from its connexion with Geometry. If the equation of a surface contain three constants which vary as parameters in subjection to any two conditions connecting them, the generated envelope will satisfy a partial differential equation of the above form. In other words any envelope of the surface

$$F(x, y, z, a, b, c) = 0$$

formed by the variation of  $a, b, c$  in subjection to two connecting conditions

$$\phi_1(a, b, c) = 0, \quad \phi_2(a, b, c) = 0$$

is necessarily an integral of a partial differential equation of the form given above.

Now this theorem is the more important, because it is only when three parameters in the equation of a surface vary in subjection to *two* relations that the envelope possesses, irrespectively of the form of the connecting relations, any *definite* character. If there be but *one* connecting relation it is possible to determine that relation so as to make the envelope assume the form of any surface whatever, and therefore the possible system of envelopes is in such case

unlimited. If there be *three* connecting relations the parameters become absolutely constant and no envelope exists.

The partial differential equation

$$Rr + Ss + Tt + U(s^2 - rt) = V$$

is remarkable also as including all the cases in which a partial differential equation of the second order admits a first integral of the form

$$u = f(v),$$

$u$  and  $v$  being definite functions of  $x, y, z, p, q$ , and  $f(v)$  arbitrary in form.

Neither of these statements is sufficiently general to constitute a theory of the genesis of the partial differential equation under consideration, but the second one is more general than the first, and is indeed sufficiently so to serve as the ground of an investigation which connects the solution of the equation in all cases with the satisfaction of a system of simultaneous ordinary differential equations of the first order and degree. And this is the ground upon which the method of the paper will rest. I propose to shew, 1st that the solution of the given equation on the assumption that a first integral of the form  $u = f(v)$  exists requires the satisfaction of a system of two partial differential equations of the first order and second degree; 2ndly that this system may be resolved into four systems, each consisting of two partial differential equations of the first order and first degree, two of which systems are irrelevant and the other two relevant; 3rdly that the solution of the two relevant systems ultimately depends on the solution of a system of ordinary differential equations of the first order, and that from these ordinary differential equations the given equation of the second order may be deduced independently of the assumption above mentioned. I shall also discuss the theory of the second integration. And I shall exemplify another method of solution connected by a remarkable law of reciprocity with the above method.

*First Investigation.*

2. PROP. I. If  $u = f(v)$  be a first integral of the equation

$$Rr + Ss + Tt + U(s^2 - rt) = V \dots \dots \dots (1),$$

then will  $u$  and  $v$ , considered as functions of  $x, y, z, p, q$ , each satisfy two partial differential equations of the form

$$\left. \begin{aligned} R \left( \frac{du}{dx} \right)^2 + S \left( \frac{du}{dx} \right) \left( \frac{du}{dy} \right) + T \left( \frac{du}{dy} \right)^2 \\ + V \left\{ \frac{du}{dp} \left( \frac{du}{dx} \right) + \frac{du}{dq} \left( \frac{du}{dy} \right) \right\} = 0 \\ R \left( \frac{du}{dx} \right) \frac{du}{dq} + T \left( \frac{du}{dy} \right) \frac{du}{dp} \\ + U \left( \frac{du}{dx} \right) \left( \frac{du}{dy} \right) + V \frac{du}{dp} \frac{du}{dq} = 0 \end{aligned} \right\} \dots \dots \dots (2),$$

in which  $\left( \frac{du}{dx} \right)$  and  $\left( \frac{du}{dy} \right)$  stand for  $\frac{du}{dx} + p \frac{du}{dz}$ , and  $\frac{du}{dy} + q \frac{du}{dz}$  respectively.

To demonstrate this proposition we shall form directly the partial differential equation of the second order of which  $u = f(v)$  is an integral and, comparing that equation with (1), deduce the conditions for the determination of  $u$  and  $v$ .

Differentiating  $u = f(v)$ , first with respect to  $x$  and secondly with respect to  $y$ , we have

$$\begin{aligned} \frac{du}{dx} + \frac{du}{dz} \frac{dz}{dx} + \frac{du}{dp} \frac{dp}{dx} + \frac{du}{dq} \frac{dq}{dx} \\ = f'(v) \left\{ \frac{dv}{dx} + \frac{dv}{dz} \frac{dz}{dx} + \frac{dv}{dp} \frac{dp}{dx} + \frac{dv}{dq} \frac{dq}{dx} \right\}, \\ \frac{du}{dy} + \frac{du}{dz} \frac{dz}{dy} + \frac{du}{dp} \frac{dp}{dy} + \frac{du}{dq} \frac{dq}{dy} \\ = f'(v) \left\{ \frac{dv}{dy} + \frac{dv}{dz} \frac{dz}{dy} + \frac{dv}{dp} \frac{dp}{dy} + \frac{dv}{dq} \frac{dq}{dy} \right\}, \end{aligned}$$

or, if we represent  $\frac{du}{dx} + p \frac{du}{dz}$  by  $\left(\frac{du}{dx}\right)$ ,  $\frac{du}{dy} + q \frac{du}{dz}$  by  $\left(\frac{du}{dy}\right)$ ,  $\frac{dp}{dx}$  by  $r$ ,  $\frac{dp}{dy}$  and  $\frac{dq}{dx}$  by  $s$ , and  $\frac{dq}{dy}$  by  $t$ ,

$$\left(\frac{du}{dx}\right) + r \frac{du}{dp} + s \frac{du}{dq} = f'(v) \left\{ \left(\frac{dv}{dx}\right) + r \frac{dv}{dp} + s \frac{dv}{dq} \right\},$$

$$\left(\frac{du}{dy}\right) + s \frac{du}{dp} + t \frac{du}{dq} = f'(v) \left\{ \left(\frac{dv}{dy}\right) + s \frac{dv}{dp} + t \frac{dv}{dq} \right\}.$$

Eliminating  $f'(v)$  we arrive at the partial differential equation of the second order,

$$\begin{aligned} & \left\{ \frac{du}{dp} \left(\frac{dv}{dy}\right) - \frac{dv}{dp} \left(\frac{du}{dy}\right) \right\} r \\ & + \left\{ \frac{du}{dq} \left(\frac{dv}{dy}\right) - \frac{dv}{dq} \left(\frac{du}{dy}\right) + \frac{dv}{dp} \left(\frac{du}{dx}\right) - \frac{du}{dp} \left(\frac{dv}{dx}\right) \right\} s \\ & + \left\{ \frac{dv}{dq} \left(\frac{du}{dx}\right) - \frac{du}{dq} \left(\frac{dv}{dx}\right) \right\} t + \left\{ \frac{du}{dq} \frac{dv}{dp} - \frac{du}{dp} \frac{dv}{dq} \right\} (s^2 - rt) \\ & = \left(\frac{du}{dy}\right) \left(\frac{dv}{dx}\right) - \left(\frac{du}{dx}\right) \left(\frac{dv}{dy}\right) \dots\dots\dots(3). \end{aligned}$$

It is seen that as respects the mode in which the quantities  $r, s, t$  are involved this equation is of the same form as the given equation (1). That it may be equivalent, its coefficients must stand to those of (1) in a common ratio  $\mu$ . This gives

$$\frac{du}{dp} \left(\frac{dv}{dy}\right) - \frac{dv}{dp} \left(\frac{du}{dy}\right) = \mu R \dots\dots\dots(a),$$

$$\frac{du}{dq} \left(\frac{dv}{dy}\right) - \frac{dv}{dq} \left(\frac{du}{dy}\right) + \frac{dv}{dp} \left(\frac{du}{dx}\right) - \frac{du}{dp} \left(\frac{dv}{dx}\right) = \mu S \dots\dots(b),$$

$$\frac{dv}{dq} \left(\frac{du}{dx}\right) - \frac{du}{dq} \left(\frac{dv}{dx}\right) = \mu T \dots\dots\dots(c),$$

$$\frac{du}{dq} \frac{dv}{dp} - \frac{du}{dp} \frac{dv}{dq} = \mu U \dots\dots\dots (d),$$

$$\left(\frac{du}{dy}\right) \left(\frac{dv}{dx}\right) - \left(\frac{du}{dx}\right) \left(\frac{dv}{dy}\right) = \mu V \dots\dots\dots (e).$$

As we have here five equations which are homogeneous with respect to the four differential coefficients of  $v$  and to  $\mu$ , it is clear that we can, by the elimination of these quantities, obtain a relation connecting the differential coefficients of  $u$  with  $R, S, T$ , &c. But the peculiar cyclical form of the functions in the first members of the above system enables us to effect this elimination so as to lead to *two* final equations independent of  $v$  and  $\mu$ .

Thus multiplying (a) by  $\left(\frac{du}{dx}\right) \frac{du}{dq}$ , (c) by  $\left(\frac{du}{dy}\right) \frac{du}{dp}$ , (d) by  $\left(\frac{du}{dx}\right) \left(\frac{du}{dy}\right)$ , and (e) by  $\frac{du}{dp} \frac{du}{dq}$ , and adding, we find, on rejecting the common factor  $\mu$ ,

$$\begin{aligned} R \left(\frac{du}{dx}\right) \frac{du}{dq} + T \left(\frac{du}{dy}\right) \frac{du}{dp} + U \left(\frac{du}{dx}\right) \left(\frac{du}{dy}\right) \\ + V \frac{du}{dp} \frac{du}{dq} = 0 \dots\dots\dots (4). \end{aligned}$$

Again, multiplying (a) by  $\left(\frac{du}{dx}\right)^2$ , (b) by  $\left(\frac{du}{dx}\right) \left(\frac{du}{dy}\right)$ , (c) by  $\left(\frac{du}{dy}\right)^2$ , and (e) by  $\left(\frac{du}{dx}\right) \frac{du}{dp} + \left(\frac{du}{dy}\right) \frac{du}{dq}$ , adding, and again rejecting the common factor  $\mu$ , we have

$$\begin{aligned} R \left(\frac{du}{dx}\right)^2 + S \left(\frac{du}{dx}\right) \left(\frac{du}{dy}\right) + T \left(\frac{du}{dy}\right)^2 \\ + V \left\{ \left(\frac{du}{dx}\right) \frac{du}{dp} + \left(\frac{du}{dy}\right) \frac{du}{dq} \right\} = 0 \dots\dots\dots (5). \end{aligned}$$

Hence,  $u$  considered as a function of  $x, y, z, p, q$  satisfies the two partial differential equations (4), (5), both which are of the first order and second degree.

As  $u$  and  $v$  enter symmetrically into the system (a), (b), &c.,  $v$  will also satisfy two partial differential equations of the same form, viz. the equations

$$\left. \begin{aligned} R \left( \frac{dv}{dx} \right) \frac{dv}{dq} + T \left( \frac{dv}{dy} \right) \frac{dv}{dp} \\ + U \left( \frac{dv}{dx} \right) \left( \frac{dv}{dy} \right) + V \frac{dv}{dp} \frac{dv}{dq} = 0 \\ R \left( \frac{dv}{dx} \right)^2 + S \left( \frac{dv}{dx} \right) \left( \frac{dv}{dy} \right) + T \left( \frac{dv}{dy} \right)^2 \\ + V \left\{ \left( \frac{dv}{dx} \right) \frac{dv}{dp} + \left( \frac{dv}{dy} \right) \frac{dv}{dq} \right\} = 0 \end{aligned} \right\} \dots (6).$$

Further, these two systems of equations constitute the *complete* system of equations resulting from the elimination of  $\mu$  from the five equations (a), (b), (c), &c.; for in their determination, no factor involving either the differential coefficients of  $u$  and  $v$ , or the quantities  $R, S, T$ , &c. has been rejected directly or indirectly.

I am not aware that the above results of elimination have been noticed before.

3. PROP. II. *The system of partial differential equations above obtained for the determination of  $u$ , viz.*

$$\left. \begin{aligned} R \left( \frac{du}{dx} \right) \frac{du}{dq} + T \left( \frac{du}{dy} \right) \frac{du}{dp} \\ + U \left( \frac{du}{dx} \right) \left( \frac{du}{dy} \right) + V \frac{du}{dp} \frac{du}{dq} = 0 \\ R \left( \frac{du}{dx} \right)^2 + S \left( \frac{du}{dx} \right) \left( \frac{du}{dy} \right) + T \left( \frac{du}{dy} \right)^2 \\ + V \left\{ \left( \frac{du}{dx} \right) \frac{du}{dp} + \left( \frac{du}{dy} \right) \frac{du}{dq} \right\} = 0 \end{aligned} \right\} \dots (7)$$

*admits of resolution into four systems, each consisting of two linear partial differential equations of the first order. Of these systems two only are relevant to the solution of the problem.*

For, multiplying the second by an indeterminate quantity  $\lambda$ , and adding the result to the first, we have

$$\begin{aligned} R\lambda \left(\frac{du}{dx}\right)^2 + (U + S\lambda) \left(\frac{du}{dx}\right) \left(\frac{du}{dy}\right) + T\lambda \left(\frac{du}{dy}\right)^2 \\ + R \left(\frac{du}{dx}\right) \frac{du}{dq} + V \frac{du}{dp} \frac{du}{dq} + T \left(\frac{du}{dy}\right) \frac{du}{dp} \\ + V\lambda \left\{ \left(\frac{du}{dx}\right) \frac{du}{dp} + \left(\frac{du}{dy}\right) \frac{du}{dq} \right\} = 0 \dots\dots\dots(8). \end{aligned}$$

Now let us see if it is possible to determine  $\lambda$  so as to make the first member of the equation resolvable into linear factors. We cannot say *à priori* that such resolution is possible as we should be able to do if that member were homogeneous and of the second degree with respect to *three* instead of with respect to the *four* subject variables

$$\left(\frac{du}{dx}\right), \left(\frac{du}{dy}\right), \left(\frac{du}{dp}\right), \left(\frac{du}{dq}\right).$$

Observing that the squares of  $\frac{du}{dp}$  and  $\frac{du}{dq}$  are wanting in the first member of (8) while those of  $\left(\frac{du}{dx}\right)$  and  $\left(\frac{du}{dy}\right)$  appear, we are led to assume as the proposed equivalent of that member an expression of the form

$$\left\{ R \left(\frac{du}{dx}\right) + m \left(\frac{du}{dy}\right) + n \frac{du}{dp} \right\} \left\{ \lambda \left(\frac{du}{dx}\right) + m' \left(\frac{du}{dy}\right) + n' \frac{du}{dq} \right\}.$$

Multiplying the factors of this expression together and then equating the coefficients with those of the first member of (8) we have

$$Rm' + \lambda m = U + S\lambda \dots\dots\dots (a),$$

$$mm' = T\lambda \dots\dots\dots (b),$$

$$\lambda n = \lambda V = mn' \dots\dots\dots (c),$$

$$Rn' = R \dots\dots\dots (d),$$

$$nm' = T \dots\dots\dots (e),$$

$$nn' = V \dots\dots\dots (f),$$

From (b), (c), (d), we find

$$n = V, \quad n' = 1, \quad m = \lambda V, \quad m' = \frac{T}{V},$$

values which will be found to satisfy (e) and (f) also, and which reduce (a) to the form

$$V^2\lambda^2 - SV\lambda + RT - UV = 0.$$

Supposing  $\lambda$  thus determined, the equation (8) becomes

$$\left\{ R \left( \frac{du}{dx} \right) + V\lambda \left( \frac{du}{dy} \right) + V \frac{du}{dp} \right\} \left\{ \lambda \left( \frac{du}{dx} \right) + \frac{T}{V} \left( \frac{du}{dy} \right) + \frac{du}{dq} \right\} = 0.$$

The result is a little simplified if we retain  $m$  in place of  $\lambda$ .

We thus find as the resolved form of the given equation

$$\left\{ R \left( \frac{du}{dx} \right) + m \left( \frac{du}{dy} \right) + V \frac{du}{dp} \right\} \left\{ m \left( \frac{du}{dx} \right) + T \left( \frac{du}{dy} \right) + V \frac{du}{dq} \right\} = 0 \dots (9),$$

$m$  being determined by the quadratic

$$m^2 - Sm + RT - UV = 0.$$

If  $m_1, m_2$  be the values of  $m$  thus found, we have

$$\left\{ R \left( \frac{du}{dx} \right) + m_1 \left( \frac{du}{dy} \right) + V \frac{du}{dp} \right\} \left\{ m_1 \left( \frac{du}{dx} \right) + T \left( \frac{du}{dy} \right) + V \frac{du}{dq} \right\} = 0,$$

$$\left\{ R \left( \frac{du}{dx} \right) + m_2 \left( \frac{du}{dy} \right) + V \frac{du}{dp} \right\} \left\{ m_2 \left( \frac{du}{dx} \right) + T \left( \frac{du}{dy} \right) + V \frac{du}{dq} \right\} = 0,$$

and these two equations are manifestly together equal to the system (7).

Now these equations can only be simultaneously satisfied by equating to 0, one factor in the first member of each; and the different combinations which are thus possible give rise to four binary systems of linear equations. Let us examine these systems separately.

If we simultaneously equate to 0 the two first factors of the left-hand members of the last two equations, we have the systems

$$R \left( \frac{du}{dx} \right) + m_1 \left( \frac{du}{dy} \right) + V \frac{du}{dp} = 0,$$

$$R \left( \frac{du}{dx} \right) + m_2 \left( \frac{du}{dy} \right) + V \frac{du}{dp} = 0,$$

a system which, when  $m_1$  and  $m_2$  are different, is reducible to the system

$$R \left( \frac{du}{dx} \right) + V \frac{du}{dp} = 0, \quad \left( \frac{du}{dy} \right) = 0.$$

It is clear that this cannot lead to a value of  $u$  satisfying the given differential equation (1), because it takes no account of the forms of  $S$ ,  $U$ , and  $T$ . Indeed if we actually eliminate

$$\left( \frac{du}{dx} \right), \quad \left( \frac{du}{dy} \right), \quad \frac{du}{dp}, \quad \frac{du}{dq}$$

from the above equations by means of the system

$$\left. \begin{aligned} \left( \frac{du}{dx} \right) + \frac{du}{dp} r + \frac{du}{dq} s &= 0 \\ \left( \frac{du}{dy} \right) + \frac{du}{dp} s + \frac{du}{dq} t &= 0 \end{aligned} \right\} \dots\dots\dots (10),$$

(derived from the assumed first integral  $u = f(v)$  by making  $f(v) = c$ , and differentiating the result first with respect to  $x$ , then with respect to  $y$ ), we find as the result

$$Vt + R(s^2 - rt) = 0.$$

Again, if we equate to 0 the two last factors of the right-hand members of (10), we have

$$m_1 \left( \frac{du}{dx} \right) + T \left( \frac{du}{dy} \right) + V \frac{du}{dq} = 0,$$

$$m_2 \left( \frac{du}{dx} \right) + T \left( \frac{du}{dy} \right) + V \frac{du}{dq} = 0,$$

which, if  $m_1$  and  $m_2$  are different, reduce to

$$T \left( \frac{du}{dy} \right) + V \frac{du}{dq} = 0, \quad \left( \frac{du}{dx} \right) = 0.$$

And it is evident that neither are these equations consistent with the given equation (1), because they take no account of  $S$ ,  $U$ , and  $R$ . The equation of the second degree to which they actually lead is

$$Vr + T(s^2 - rt) = 0.$$

There remain then the two systems formed by combining the first factor of each one of the first members with the second factor of the other, viz.

$$\left. \begin{aligned} R \left( \frac{du}{dx} \right) + m_1 \left( \frac{du}{dy} \right) + V \frac{du}{dp} &= 0 \\ m_2 \left( \frac{du}{dx} \right) + T \left( \frac{du}{dy} \right) + V \frac{du}{dq} &= 0 \end{aligned} \right\} \dots\dots\dots (11),$$

$$\left. \begin{aligned} R \left( \frac{du}{dx} \right) + m_2 \left( \frac{du}{dy} \right) + V \frac{du}{dp} &= 0 \\ m_1 \left( \frac{du}{dx} \right) + T \left( \frac{du}{dy} \right) + V \frac{du}{dq} &= 0 \end{aligned} \right\} \dots\dots\dots (12).$$

That these systems are relevant to the solution of the problem under consideration may be shewn by eliminating from either of them by means of (10) the quantities

$$\left(\frac{du}{dx}\right), \left(\frac{du}{dy}\right), \frac{du}{dp}, \frac{du}{dq}.$$

The actual result will be

$$V\{Rr + Ss + Tt + U(s^2 - rt) - V\} = 0 \dots\dots\dots (13),$$

which, except in the particular case of  $V=0$ , reduces to the given equation.

More generally, if in the equation

$$u = f(v)$$

$u$  and  $v$  are any *distinct* solutions of the system (11), the same result of elimination may be deduced. For  $v$  by hypothesis satisfies the equations

$$R \left(\frac{dv}{dx}\right) + m_1 \left(\frac{dv}{dy}\right) + V \frac{dv}{dp} = 0,$$

$$m_2 \left(\frac{dv}{dx}\right) + T \left(\frac{dv}{dy}\right) + V \frac{dv}{dq} = 0.$$

Subtract these equations multiplied by  $f'(v)$  from the corresponding equations of (11), and representing  $u - f(v)$  by  $W$ , we have

$$R \left(\frac{dW}{dx}\right) + m_1 \left(\frac{dW}{dy}\right) + V \frac{dW}{dp} = 0,$$

$$m_2 \left(\frac{dW}{dx}\right) + T \left(\frac{dW}{dy}\right) + V \frac{dW}{dq} = 0,$$

which being of the same form as (11) it follows that

$$W = 0 \text{ or } u - f(v) = 0$$

also leads to the partial differential equation of the second order (13).

4. PROP. III. *To reduce the determination of the first integrals of (1) to the solution of a system of ordinary differential equations.*

Each of the systems (11), (12) presents  $u$  as satisfying simultaneously two linear partial differential equations of the first order.

To deduce the value of  $u$  thus conditioned it will obviously suffice to multiply in each system one of the partial differential equations by an indeterminate multiplier  $\lambda$ , to add the result to the other equation so as to form a new equation which will, like those from which it is formed, be linear and of the first order, and which on account of the indeterminate character of  $\lambda$  will be equivalent to the two. From the auxiliary equations which we obtain in the process of solution,  $\lambda$  must be eliminated.

If in this way we combine the equations of the system (11), we have, on arranging the resulting equation according to the differential coefficients of  $u$ ,

$$\begin{aligned} (R + \lambda m_2) \frac{du}{dx} + (m_1 + \lambda T) \frac{du}{dy} \\ + \left\{ Rp + m_1 q + \lambda (Tq + m_2 p) \right\} \frac{du}{dz} \\ + V \frac{du}{dp} + \lambda V \frac{du}{dq} = 0. \end{aligned}$$

Hence we have the auxiliary equations

$$\frac{dx}{R + \lambda m_2} = \frac{dy}{m_1 + \lambda T} = \frac{dp}{V} = \frac{dq}{\lambda V} = \frac{dz}{Rp + m_1 q + \lambda (Tq + m_2 p)},$$

$$du = 0,$$

and it is to be remembered that  $m_1, m_2$  are the roots of the equation

$$m^2 - Sm + RT - UV = 0.$$

Eliminating  $\lambda$  from the first four of the above equations we have

$$\left. \begin{aligned} Udq + m_1 dx - Rdy &= 0 \\ Udp + m_2 dy - Tdx &= 0 \\ dz - p dx - q dy &= 0 \end{aligned} \right\} \dots\dots\dots (I).$$

This then is the system of ordinary differential equations deduced from (11) upon the integration of which the determination of  $u$  will depend.

A similar system, differing from the above only in the mutual transposition of  $m_1$  and  $m_2$ , is given by (12), viz.

$$\left. \begin{aligned} Udq + m_2 dx - Rdy &= 0 \\ Udp + m_1 dy - Tdx &= 0 \\ dz - p dx - q dy &= 0 \end{aligned} \right\} \dots\dots\dots (II).$$

If from either of these systems we can deduce two integrals of the forms

$$u = a, \quad v = b,$$

it is obvious, from what precedes, that

$$u = f(v)$$

will constitute a first integral of the proposed (1), and there being two systems in question, two such first integrals, each involving an arbitrary constant may coexist.

5. PROP. IV. *To deduce the second integral of (1).*

It will be necessary to consider separately the cases in which  $m_1$  and  $m_2$  are equal and unequal.

First let  $m_1$  and  $m_2$  be equal.

Both the systems (I), (II) reduce to a single system which may be expressed in the form

$$\left. \begin{aligned} dp &= \frac{T}{U} dx - \frac{m}{U} dy \\ dq &= -\frac{m}{U} dx + R dy \\ dz &= p dx + q dy \end{aligned} \right\} \dots\dots\dots (14).$$

Now, since the condition  $\frac{dp}{dy} = \frac{dq}{dx}$  is here satisfied, it is manifest that if from any two integrals of the above system of the forms  $u = a$ ,  $v = b$ , simultaneous values of  $p$  and  $q$  be determined, these values will render the third equation of the system integrable, and the effect of its integration will be virtually to determine  $z$  as a function of  $x$ ,  $y$ , and three arbitrary constants, viz.  $a$ ,  $b$ , and a constant  $c$  introduced in the last integration. Let us represent the result in the form

$$z = \phi(x, y, a, b, c) \dots \dots \dots (15).$$

Now what relation will this result bear to the general solution of the partial differential equation given, to the solution which we should obtain by integrating, not the particular equations  $u = a$ ,  $v = b$ , but the general first integral  $u = f(v)$ , which includes them both.

To integrate the equation  $u = f(v)$  it suffices to deduce any particular equation involving an arbitrary constant  $b$ , which, in conjunction with  $u = f(v)$  will render

$$dz - p dx - q dy = 0$$

integrable, and to integrate the last equation regarding the arbitrary constant of integration as an arbitrary function of  $b$ . The result is a complete primitive in which, by the variation of  $b$  as a parameter the general integral is implicitly involved.

Now either of the equations  $u = a$ ,  $v = b$  will, in conjunction with  $u = f(v)$  determine  $p$  and  $q$  so as to make

$$dz - p dx - q dy = 0$$

integrable. Take the equation  $v = b$ , then  $u = f(v)$  reduces to

$$u = f(b).$$

Thus, in place of the equations  $u = a$ ,  $v = b$ , of the previous section, we have

$$u = f(b), \quad v = b$$

for the determination of  $p$  and  $q$ . The constant  $c$  introduced in the final integration becomes also, according to the above theory, a function of  $b$ , and the complete primitive is of the form

$$z = \phi \{x, y, b, f(b), \psi(b)\} \dots \dots \dots (16),$$

while the general integral is found by eliminating  $b$  between this equation and its differential with respect to  $b$ .

The general integral therefore represents the envelope of the surface represented by (15),  $a, b, c$  being parameters subject to any two connecting conditions.

As  $m_1, m_2$  are supposed equal, a necessary condition of the possibility of this species of integration is that

$$S^2 - 4(RT - UV) = 0 \dots \dots \dots (17),$$

the value of  $m$  is  $\frac{S}{2}$ , and the system (14) reduces to

$$\left. \begin{aligned} Udp + \frac{S}{2} dy - Tdx &= 0 \\ Udq + \frac{S}{2} dx - Rdy &= 0 \\ dz - pdx - qdy &= 0 \end{aligned} \right\} \dots \dots \dots (18).$$

*We conclude therefore that if (17) be satisfied and we can from (18) deduce a value of  $z$  in terms of  $x, y$ , and three arbitrary constants, the equation expressing that value will be a complete primitive, and the general integral will be found by making the constants vary in subjection to two arbitrary conditions.*

Ex. Let the given equation be

$$xqr + ypt + xy(s^2 - rt) = pq.$$

Here  $R = xq, S = 0, T = yp, U = xy, V = pq.$

The condition (17) is satisfied, and (18) becomes

$$\begin{aligned}xydp - ypdx &= 0, \\xydq - xqdy &= 0, \\dz - pdx - qdy &= 0.\end{aligned}$$

From the two first of these we find

$$p = ax, \quad q = by,$$

whence from the third,

$$z = \frac{ax^2}{2} + \frac{by^2}{2} + c.$$

This is the complete primitive, and the general primitive consists of all possible equations derived from this by making  $a, b, c$  vary in subjection to two conditions.

Ex. 2. Given

$$\begin{aligned}(1 + q^2)r - 2pqs + (1 + p^2)t - \frac{s^2 - rt}{(1 + p^2 + q^2)^{\frac{1}{2}}} \\= - (1 + p^2 + q^2)^{\frac{3}{2}}.\end{aligned}$$

Here the equation for  $m$  reduces to

$$m^2 + 2pqm + p^2q^2 = 0,$$

whence  $m = -pq$ , and the system (18) gives

$$\begin{aligned}\frac{dq}{(1 + p^2 + q^2)^{\frac{1}{2}}} + pqdx + (1 + q^2)dy &= 0, \\ \frac{dp}{(1 + p^2 + q^2)^{\frac{1}{2}}} + pqdy + (1 + p^2)dx &= 0.\end{aligned}$$

Subtracting the upper equation multiplied by  $pq$  from the lower one multiplied by  $1 + q^2$ , and dividing by  $1 + p^2 + q^2$ , we have

$$dx + \frac{(1 + q^2) dp - pq dq}{(1 + p^2 + q^2)^{\frac{3}{2}}} = 0,$$

whence

$$x + \frac{p}{\sqrt{(1 + p^2 + q^2)}} = a.$$

In like manner,

$$y + \frac{q}{\sqrt{(1 + p^2 + q^2)}} = b.$$

Hence determining  $p$  and  $q$ ,

$$dz = - \frac{(x - a) dx + (y - b) dy}{\sqrt{\{1 - (x - a)^2 - (y - b)^2\}}}.$$

Therefore  $(x - a)^2 + (y - b)^2 + (z - c)^2 = 1.$

From this form of the complete primitive it is evident that the general integral will represent all possible tubular surfaces formed by the motion through space of a sphere of constant radius unity.

Secondly, let  $m_1$  and  $m_2$  be unequal.

Then since, in neither of the systems (I) and (II) is the condition  $\frac{dp}{dy} = \frac{dq}{dx}$  satisfied, from neither system separately can values of  $p$  and  $q$  be obtained which make  $dz = p dx + q dy$  integrable.

But, as will be shewn, any two integrals obtained, the one from the one system and the other from the other, will give values of  $p$  and  $q$  which will render  $dz = p dx + q dy$  in-

tegrable, and the general solution will consist of all possible integrals of the latter equation thus obtained.

Or if the *complete* first integral of either system be combined with any *particular* integral involving an arbitrary constant obtained from the other, the two will furnish values of  $p$  and  $q$  which render  $dz = pdx + qdy$  integrable, and its integral will be a complete primitive involving *one* arbitrary function in its expressed form, *another* in the connexion of its two constants; the general primitive being found in the usual way by making the constants vary as parameters in subjection to a single arbitrary connecting condition.

In fact it may be shewn that if we attempt by the process of Charpit or Lagrange to integrate the partial differential equation of the first order  $u = f(v)$ , deduced we will here suppose from the system (I), we virtually construct the system (II) in the auxiliary equations upon which the process of solution turns. I have obtained a direct proof of this proposition, but I think it preferable and at the same time sufficient to direct attention to the prior ground upon which it rests in the relations of the systems of partial differential equations (11), (12) from which the systems of ordinary differential equations (I), (II) are derived.

Let  $P = 0$  represent any integral of the system (11), and  $Q = 0$  any integral of the system (12). Then we have

$$\begin{aligned} -V \frac{dP}{dp} &= R \left( \frac{dP}{dx} \right) + m_1 \left( \frac{dP}{dy} \right) \\ -V \frac{dP}{dq} &= m_2 \left( \frac{dP}{dx} \right) + T \left( \frac{dP}{dy} \right) \\ -V \frac{dQ}{dp} &= R \left( \frac{dQ}{dx} \right) + m_2 \left( \frac{dQ}{dy} \right) \\ -V \frac{dQ}{dq} &= m_1 \left( \frac{dQ}{dx} \right) + T \left( \frac{dQ}{dy} \right). \end{aligned}$$

Hence we deduce

$$\begin{aligned}
 & -V \left\{ \frac{dP}{dp} \left( \frac{dQ}{dx} \right) - \frac{dQ}{dp} \left( \frac{dP}{dx} \right) + \frac{dP}{dq} \left( \frac{dQ}{dy} \right) - \frac{dQ}{dq} \left( \frac{dP}{dy} \right) \right\} \\
 & = \left\{ R \left( \frac{dP}{dx} \right) + m_1 \left( \frac{dP}{dy} \right) \right\} \left( \frac{dQ}{dx} \right) - \left\{ R \left( \frac{dQ}{dx} \right) + m_2 \left( \frac{dQ}{dy} \right) \right\} \left( \frac{dP}{dx} \right) \\
 & + \left\{ m_2 \left( \frac{dP}{dx} \right) + T \left( \frac{dP}{dy} \right) \right\} \left( \frac{dQ}{dy} \right) - \left\{ m_1 \left( \frac{dQ}{dx} \right) + T \left( \frac{dQ}{dy} \right) \right\} \left( \frac{dP}{dy} \right).
 \end{aligned}$$

The second member of this equation is identically 0. Hence dividing by  $V$  we have

$$\frac{dP}{dp} \left( \frac{dQ}{dx} \right) - \frac{dQ}{dp} \left( \frac{dP}{dx} \right) + \frac{dP}{dq} \left( \frac{dQ}{dy} \right) - \frac{dQ}{dq} \left( \frac{dP}{dy} \right) = 0. \dots (19).$$

But this is the known condition under which the values of  $p$  and  $q$  deduced from the equations  $P=0$ ,  $Q=0$  make  $dz = p dx + q dy$  integrable; see Chap. XIV. Art. 13, Equation (36).

*We conclude then that if from the systems (I), (II) we can deduce two corresponding systems of integrals*

$$u_1 = \alpha_1, \quad v_1 = b_1,$$

$$u_2 = \alpha_2, \quad v_2 = b_2,$$

*then will the first integrals of (1) be*

$$u_1 = f_1(v_1), \quad u_2 = f_2(v_2),$$

*while the second integral will consist of all possible relations obtained either 1st by specifying the forms of  $f_1, f_2$  and obtaining  $p$  and  $q$  as functions of  $x$  and  $y$  and integrating  $dz = p dx + q dy$ , or 2ndly, by specifying one of the functions  $f_1, f_2$ , leaving the other arbitrary, determining  $p, q$ , integrating  $dz = p dx + q dy$ , and regarding the final constant of integration as an arbitrary parameter.*

Ex. Given  $ar + bs + ct + e (s^2 - rt) = h$ , the coefficients being constant.

Here  $R = a$ ,  $S = b$ ,  $T = c$ ,  $U = e$ ,  $V = h$ .

Hence  $m_1$ ,  $m_2$  are the roots of

$$m^2 - bm + ac - eh = 0,$$

and the systems (I), (II) give

$$\left. \begin{aligned} edq + m_1 dx - ady &= 0 \\ edp + m_2 dy - cdx &= 0 \end{aligned} \right\},$$

$$\left. \begin{aligned} edq + m_2 dx - ady &= 0 \\ edp + m_1 dy - cdx &= 0 \end{aligned} \right\}.$$

Whence the first integrals are

$$eq + m_1 x - ay = f_1 (ep + m_2 y - cx),$$

$$eq + m_2 x - ay = f_2 (ep + m_1 y - cx),$$

from which all possible second integrals are to be derived in the modes above explained.

Let us take the second of those modes and give to the second of the above first integrals the particular form

$$ep + m_1 y - cx = C,$$

$C$  being an arbitrary constant. From this, and from the other integral, left in its complete form, we have

$$p = \frac{cx - m_1 y + C}{e}, \quad q = \frac{ay - m_1 x + f_1 \{(m_2 - m_1) y + C\}}{e},$$

whence, substituting in the formula  $dz = p dx + q dy$ , integrating, replacing the arbitrary form

$$\int f_1(t) dt \text{ by } (m_2 - m_1) \phi(t),$$

and introducing an arbitrary function of  $C$  for the arbitrary constant, we have

$$z = \frac{1}{e} \left[ \frac{cx^2}{2} - m_1 xy + \frac{ay^2}{2} + Cx + \phi \{ (m_2 - m_1) y + C \} \right] + \psi(C)$$

for a complete primitive. The general primitive consists of all possible relations obtained by eliminating  $C$  between the above equation and

$$0 = \frac{1}{e} [x + \phi' \{ (m_2 - m_1) y + C \}] + \psi'(C),$$

when the forms of  $\phi$  and  $\psi$  are specified.

### *Second Investigation.*

6. If from the equation

$$Rr + Ss + Tt + U(s^2 - rt) = V \dots \dots \dots (20),$$

we eliminate  $r$  and  $t$  by means of the equations

$$dp = rdx + sdy,$$

$$dq = sdx + tdy,$$

the result will be

$$\begin{aligned} & [Rdy^2 - Sdx dy + Tdx^2 - U(dpdx + dqdy)] s \\ & = Rdpdy + Tdqdx - Udpdq - Vdxdy \dots \dots (21). \end{aligned}$$

There are different considerations (all of them however involving, as I have been led to think, a more or less explicit reference to some theory of the genesis of the given partial differential equation) which indicate that its solution depends upon that of the equations obtained by equating to 0 the part affected and the part not affected by  $s$ , viz. upon the solution of the equations

$$Rdy^2 - Sdx dy + Tdx^2 - U(dpdx + dqdy) = 0 \dots \dots (22),$$

$$Rdpdy + Tdqdx - Udpdq - Vdxdy = 0 \dots \dots \dots (23).$$

Without entering into these considerations let us inquire what consequences may be deduced from these equations assumed to be true.

It is seen that these equations are connected by a remarkable reciprocity with the partial differential equations (7). They will in fact be converted into these equations if we change

$$dx, dy, dp, dq, U, V, S \dots\dots\dots (24),$$

into

$$-\frac{du}{dy}, -\frac{du}{dx}, \frac{du}{dq}, \frac{du}{dp}, V, U, -S \dots\dots\dots (25)$$

respectively. From this formal connexion it follows that if we multiply (22) by  $\lambda$  and add to the result (23), we shall be able to determine  $\lambda$  so as to permit the resolution of the equation thus formed into linear factors. Ultimately we shall, as appears from Art. 3, reduce the system (22), (23) to an equivalent system of the form

$$(-Rdy - m_1dx + Udq) (-m_1dy - Tdx + Udp) = 0,$$

$$(-Rdy - m_2dx + Udq) (-m_2dy - Tdx + Udp) = 0,$$

$m_1$  and  $m_2$  being determined by the equation

$$m^2 + Sm + RT - UV = 0,$$

or, changing the sign of  $m$ ,

$$\left. \begin{aligned} (-Rdy + m_1dx + Udq) (m_1dy - Tdx + Udp) &= 0 \\ (-Rdy + m_2dx + Udq) (m_2dy - Tdx + Udp) &= 0 \end{aligned} \right\} \dots (26),$$

$m_1$  and  $m_2$  being as in the former investigation roots of

$$m^2 - Sm + RT - UV = 0.$$

Equating to 0 the *corresponding* factors of the first members we have

$$\left. \begin{aligned} -Rdy + m_1dx + Udq &= 0 \\ -Rdy + m_2dx + Udq &= 0 \end{aligned} \right\},$$

$$\left. \begin{aligned} m_1dy - Tdx + Udp &= 0 \\ m_2dy - Tdx + Udp &= 0 \end{aligned} \right\}.$$

The first of these,  $m_1$  and  $m_2$  being different, is resolvable into

$$Udq - Rdy = 0, \quad dx = 0;$$

the second into

$$Udp - Tdx = 0, \quad dy = 0,$$

and it is obvious that neither of these can lead to the given partial differential equation (1). The first of them combined with the equations

$$dp = rdx + sdy, \quad dq = sdx + tdy \dots\dots\dots (27),$$

leads in fact to the partial differential equation

$$R - Ut = 0 \dots\dots\dots (28),$$

the second in like manner leads to

$$T - Ur = 0 \dots\dots\dots (29).$$

But equating to 0 the *non-corresponding* factors of the first members of (26) we have

$$\left. \begin{aligned} -Rdy + m_1 dx + Udq &= 0 \\ m_2 dy - Tdx + Udp &= 0 \end{aligned} \right\},$$

$$\left. \begin{aligned} m_1 dy - Tdx + Udp &= 0 \\ -Rdy + m_2 dx + Udq &= 0 \end{aligned} \right\}.$$

Now these systems when completed by the equation  $dz = pdx + qdy$  agree with the systems (I), (II) deduced in the previous investigation.

It remains to shew that these systems actually lead to the given partial differential equation (1) *directly*. Eliminating from either of them, combined with the system (27) the differentials  $dx, dy, dp, dq$ , we shall have as the result

$$U \{ Rr + Ss + Tt + U (s^2 - rt) - V \} = 0 \dots\dots\dots (30),$$

which, rejecting the factor  $U$ , as from (13) we rejected  $V$ , is the differential equation proposed.

*Ground of the Reciprocity above noticed.*

7. The reciprocity above noticed is not of a primary character, but is founded upon two prior laws which I shall proceed to demonstrate.

If from the partial differential equations of the system (7) we eliminate  $V$  and substitute the resulting equation in the place of the first equation of the system we shall obtain the equivalent system

$$\left. \begin{aligned} R \left( \frac{du}{dq} \right)^2 - S \frac{du}{dq} \frac{du}{dp} + T \left( \frac{du}{dp} \right)^2 \\ + U \left\{ \left( \frac{du}{dx} \right) \frac{du}{dp} + \left( \frac{du}{dy} \right) \frac{du}{dq} \right\} = 0 \\ R \left( \frac{du}{dx} \right)^2 + S \left( \frac{du}{dx} \right) \left( \frac{du}{dy} \right) + T \left( \frac{du}{dy} \right)^2 \\ + V \left\{ \left( \frac{du}{dx} \right) \frac{du}{dp} + \left( \frac{du}{dy} \right) \frac{du}{dq} \right\} = 0 \end{aligned} \right\} \dots (31).$$

These equations are both symmetrical and it will be observed that they are convertible the one into the other by changing

$$\frac{du}{dq}, \frac{du}{dp}, \frac{du}{dx}, \frac{du}{dy}, U, S, V \dots \dots \dots (32),$$

into

$$\frac{du}{dx}, \frac{du}{dy}, \frac{du}{dq}, \frac{du}{dp}, V, -S, U \dots \dots \dots (33),$$

respectively. This is a law of reciprocity which connects solely the differential coefficients of  $u$  and the coefficients  $U, S, V$  of the original equation.

Again  $u = 0$  is by hypothesis a solution of the given partial differential equation. Regarding it however simply as an

equation which is *true* and the truth of which is consistent with that of the equations

$$\left. \begin{aligned} dp &= rdx + sdy \\ dq &= sdx + tdy \end{aligned} \right\} \dots\dots\dots (34),$$

and differentiating it first with respect to  $x$ , secondly with respect to  $y$ , we have

$$\frac{du}{dx} + \frac{du}{dz} \frac{dz}{dx} + \frac{du}{dp} \frac{dp}{dx} + \frac{du}{dq} \frac{dq}{dx} = 0,$$

$$\frac{du}{dy} + \frac{du}{dz} \frac{dz}{dy} + \frac{du}{dp} \frac{dp}{dy} + \frac{du}{dq} \frac{dq}{dy} = 0,$$

equations to which we may give the form

$$\begin{aligned} -\left(\frac{du}{dx}\right) &= r \frac{du}{dp} + s \frac{du}{dq} \\ -\left(\frac{du}{dy}\right) &= s \frac{du}{dp} + t \frac{du}{dq}. \end{aligned}$$

Now this system is of the same form as the system (27) and will agree with it if we change

$$-\frac{du}{dx}, -\frac{du}{dy}, \frac{du}{dp}, \frac{du}{dq} \dots\dots\dots (35),$$

into

$$dp, dq, dx, dy \dots\dots\dots (36),$$

respectively—a change which does not affect the coefficients of the given equation, and which is therefore the expression of a law of reciprocity distinct from that last noted. The combination of these two laws does however lead to the law exemplified in the researches of the previous Article; see (24) and (25).

The question here arises whether it would not have been better to employ from the first the symmetrical forms (31) of

the partial differential equations of the first order and second degree upon which  $u$  depends, than the unsymmetrical forms (7). It was indeed from the symmetrical forms that the chief results of this paper were originally obtained, but the unsymmetrical forms lead to the same end in a simpler way, and therefore they have been made use of in the present memoir.

It may be proper to notice, in concluding this section, that the symmetrical forms in ordinary differentials would have emerged in place of the unsymmetrical ones of (22) and (23), if the quantity  $s^2 - rt$  had been retained instead of  $s$ . The equations

$$dp = rdx + sdy, \quad dq = sdx + tdy,$$

enable us in fact to reduce the given equation (20) to the form

$$\begin{aligned} & Rdp^2 + Sdpdq + Tdq^2 - V(dpdx + dqdy) \\ &= (s^2 - rt) \{Rdy^2 - Sdxdy + Tdx^2 - U(dpdx + dqdy)\}. \end{aligned}$$

Hence arises the symmetrical system

$$\begin{aligned} & Rdp^2 + Sdpdq + Tdq^2 - V(dpdx + dqdy) = 0, \\ & Rdy^2 - Sdxdy + Tdx^2 - U(dpdx + dqdy) = 0, \end{aligned}$$

which is connected with the system (31) by the single law of reciprocity expressed in (35) and (36).

### *Postscript.*

8. At the time when the above investigations engaged my attention I was totally unaware that the subject of them had been discussed by Ampère (*Journal de l'Ecole Polytechnique*, Tom. xi.) and recently by Professor De Morgan (*Cambridge Philosophical Transactions*, Vol. ix. Pt. iv.). I feel it therefore incumbent upon me to state why after acquainting my-

self with the results of their labours, I offer this paper for publication.

The method of Professor de Morgan so far resembles the first method of this paper, and that of Ampère the second, that while the former makes the solution of the problem depend directly upon that of simultaneous partial differential equations of the first order, the latter makes it to depend directly upon the solution of simultaneous ordinary differential equations of the first order. The formal connexion of these methods by the law of reciprocity is, I believe, established for the first time in this paper. The system of partial differential equations of the second degree (7) has not, so far as I am aware, been given before.

But a point which I think of deep importance is the following. By connecting, as in this paper, the differential equations of the second degree, whether ordinary or partial, by an indefinite multiplier which is afterwards determined so as to admit of the resolution of the system into its component linear elements, we assure ourselves that each step of the solution offers a complete sequence to that which has gone before, and it only remains then to separate the different elements and determine whether they are relevant or irrelevant to the end in view. That any such distinction exists has not, so far as I am aware, been noticed before. And it seems to me the more important that it should be noticed because the solution of partial differential equations in cases far more general than those above considered seems to depend upon the satisfaction of simultaneous differential equations of a degree higher than the first. I have in fact by an application of the Calculus of Variations arrived at the conclusion that the theory of the solution of all partial differential equations of the second order, whatever the number of variables may be, is very intimately connected with the satisfaction of a system of differential equations of the type

$$\frac{dF}{dr} dy^2 - \frac{dF}{ds} dx dy + \frac{dF}{dt} dx^2 = 0,$$

$F=0$  representing the given partial differential equation,  $x$  and  $y$  any two of the independent variables, and  $r, s, t$  the

second differential coefficients of the dependent variable with respect to  $x$  and  $y$ .

I may perhaps at some future day resume the subject, together with an inquiry into the theory of the solution of the partial differential equation of this paper, when the conditions under which the auxiliary equations (I), (II) are supposed to be integrable are not satisfied.

9. NOTE. It may be desirable to establish directly the converse form of one of the results of Proposition IV. For this object we shall shew that the equation of the envelope of

$$z = \phi(x, y, a, b, c) \dots \dots \dots (1),$$

where  $a, b, c$  are connected by any two conditions of the forms

$$\psi(a, b, c) = 0, \quad \chi(a, b, c) = 0,$$

will satisfy a partial differential equation of the form

$$Rr + Ss + Tt + U(s^2 - rt) = V \dots \dots \dots (2),$$

in which also

$$S^2 = 4(RT - UV).$$

Differentiating (1) we have

$$\left. \begin{aligned} p &= \frac{d\phi}{dx} + \frac{d\phi}{da} \frac{da}{dx} + \frac{d\phi}{db} \frac{db}{dx} + \frac{d\phi}{dc} \frac{dc}{dx} \\ q &= \frac{d\phi}{dy} + \frac{d\phi}{da} \frac{da}{dy} + \frac{d\phi}{db} \frac{db}{dy} + \frac{d\phi}{dc} \frac{dc}{dy} \end{aligned} \right\}$$

and by the nature of an envelope these reduce to

$$p = \frac{d\phi}{dx}, \quad q = \frac{d\phi}{dy} \dots \dots \dots (3).$$

Again differentiating these equations with respect to  $x$  and  $y$ , and writing for simplicity

$$\begin{aligned} \frac{d^2\phi}{dadx} &= A, & \frac{d^2\phi}{dbdx} &= B, & \frac{d^2\phi}{dcdx} &= C, \\ \frac{d^2\phi}{dady} &= A', & \frac{d^2\phi}{dbdy} &= B', & \frac{d^2\phi}{dcdy} &= C', \end{aligned}$$

we have

$$\begin{aligned} r &= \frac{d^2\phi}{dx^2} + A \frac{da}{dx} + B \frac{db}{dx} + C \frac{dc}{dx}, \\ s &= \frac{d^2\phi}{dxdy} + A \frac{da}{dy} + B \frac{db}{dy} + C \frac{dc}{dy}, \\ s &= \frac{d^2\phi}{dxdy} + A' \frac{da}{dx} + B' \frac{db}{dx} + C' \frac{dc}{dx}, \\ t &= \frac{d^2\phi}{dy^2} + A' \frac{da}{dy} + B' \frac{db}{dy} + C' \frac{dc}{dy}. \end{aligned}$$

Hence we find

$$\begin{aligned} &\left(s - \frac{d^2\phi}{dxdy}\right)^2 - \left(r - \frac{d^2\phi}{dx^2}\right)\left(t - \frac{d^2\phi}{dy^2}\right) \\ &= \left(A \frac{da}{dy} + B \frac{db}{dy} + C \frac{dc}{dy}\right)\left(A' \frac{da}{dx} + B' \frac{db}{dx} + C' \frac{dc}{dx}\right) \\ &\quad - \left(A \frac{da}{dx} + B \frac{db}{dx} + C \frac{dc}{dx}\right)\left(A' \frac{da}{dy} + B' \frac{db}{dy} + C' \frac{dc}{dy}\right) \\ &= (AB' - A'B) \left(\frac{da}{dy} \frac{db}{dx} - \frac{da}{dx} \frac{db}{dy}\right) \\ &\quad + (BC' - B'C) \left(\frac{db}{dy} \frac{dc}{dx} - \frac{db}{dx} \frac{dc}{dy}\right) \\ &\quad + (CA' - C'A) \left(\frac{dc}{dy} \frac{da}{dx} - \frac{dc}{dx} \frac{da}{dy}\right). \end{aligned}$$

Now since  $a, b, c$  are connected by two conditions, so that  $b$  and  $c$  are functions of  $x$  and  $y$  only as being functions of  $a$ , we have

$$\begin{aligned} \frac{da}{dy} \frac{db}{dx} - \frac{da}{dx} \frac{db}{dy} &= 0, & \frac{db}{dy} \frac{dc}{dx} - \frac{db}{dx} \frac{dc}{dy} &= 0, \\ \frac{dc}{dy} \frac{da}{dx} - \frac{dc}{dx} \frac{da}{dy} &= 0. \end{aligned}$$

Thus the above equation reduces to

$$\left(s - \frac{d^2\phi}{dx dy}\right)^2 - \left(r - \frac{d^2\phi}{dx^2}\right)\left(t - \frac{d^2\phi}{dy^2}\right) = 0,$$

or

$$\frac{d^2\phi}{dy^2}r - 2\frac{d^2\phi}{dx dy}s + \frac{d^2\phi}{dx^2}t + s^2 - rt = \frac{d^2\phi}{dx^2}\frac{d^2\phi}{dy^2} - \left(\frac{d^2\phi}{dx dy}\right)^2 \dots (4).$$

This equation is of the general form (2). Its coefficients  $\frac{d^2\phi}{dy^2}$ , &c. are determinable as functions of  $x, y, z, p, q$  when the form of the complete primitive (1) is given. For this purpose the complete primitive with the two derived equations (3) suffice.

Again, comparing (4) with (2) we have as the conditions of their equivalence

$$\frac{R}{\frac{d^2\phi}{dy^2}} = \frac{S}{-2\frac{d^2\phi}{dx dy}} = \frac{T}{\frac{d^2\phi}{dx^2}} = U = \frac{V}{\frac{d^2\phi}{dx^2}\frac{d^2\phi}{dy^2} - \left(\frac{d^2\phi}{dx dy}\right)^2},$$

conditions which suppose  $R, S, T, U, V$  connected by the relation

$$S^2 - 4(RT - UV) = 0.$$

## CHAPTER XXX.

### ADDITIONS TO CHAPTER XVII.

[THE present Chapter consists of additions to Chapter XVII. Art. 1 was intended to follow Chap. XVII. Art. 1.]

1. The theory of the solution of linear differential equations in a series flows very beautifully from their symbolical expression. It is usual in treating this subject to assume the form of the series, and deduce from the differential equation the law of its coefficients; but the symbolical form of the differential equation determines in reality the form of the solution as well as the law of derivation of its successive terms.

Let us begin with the binomial equation

$$f_0(D) u - f_1(D) \epsilon^{r\theta} u = 0.$$

Operating on both sides with  $\{f_0(D)\}^{-1}$ , we have

$$u - \phi(D) \epsilon^{r\theta} u = \{f_0(D)\}^{-1} 0,$$

in which

$$\phi(D) = \frac{f_1(D)}{f_0(D)}.$$

Hence

$$\{1 - \phi(D) \epsilon^{r\theta}\} u = \{f_0(D)\}^{-1} 0.$$

Now  $\{f_0(D)\}^{-1} 0$  will be determined by the solution of a linear differential equation with constant coefficients, and will be necessarily of the form

$$AP + BQ + CR + \dots,$$

in which  $A, B, C, \dots$  are arbitrary constants, and  $P, Q, R, \dots$  are functions of the independent variable.

We have then

$$\{1 - \phi(D) \epsilon^{r\theta}\} u = AP + BQ + CR + \dots,$$

therefore  $u = \{1 - \phi(D) \epsilon^{r\theta}\}^{-1} (AP + BQ + CR + \dots)$ .

Now let us represent  $\phi(D) \epsilon^{r\theta}$  by  $\rho$ ; then

$$\begin{aligned} u &= (1 - \rho)^{-1} (AP + BQ + CR + \dots) \\ &= (1 + \rho + \rho^2 + \rho^3 + \dots) (AP + BQ + CR + \dots) \\ &= A(1 + \rho + \rho^2 + \rho^3 + \dots) P \\ &\quad + B(1 + \rho + \rho^2 + \rho^3 + \dots) Q \\ &\quad + C(1 + \rho + \rho^2 + \rho^3 + \dots) R \\ &\quad + \dots \end{aligned}$$

Represent the first line of the above expression by  $u_1$ , then since

$$\begin{aligned} \rho^m &= \phi(D) \epsilon^{r\theta} \phi(D) \epsilon^{r\theta} \dots m \text{ times} \\ &= \epsilon^{mr\theta} \phi(D + mr) \phi(D + mr - r) \dots \phi(D + r), \end{aligned}$$

we have

$$\begin{aligned} u_1 &= A \{P + \epsilon^{r\theta} \phi(D + r) P + \epsilon^{2r\theta} \phi(D + 2r) \phi(D + r) P \\ &\quad + \epsilon^{3r\theta} \phi(D + 3r) \phi(D + 2r) \phi(D + r) P + \dots\}, \end{aligned}$$

in which it only remains to perform the operations indicated by  $\phi(D + r)$ , by  $\phi(D + 2r) \phi(D + r)$ , ... on the function  $P$ .

Let us in the first place suppose the symbolic function  $f_0(D)$  to be of the form  $(D - a)(D - b) \dots$ ; then

$$\{f_0(D)\}^{-1} 0 = A\epsilon^{a\theta} + B\epsilon^{b\theta} + \dots$$

Here  $P = \epsilon^{a\theta}$ . Hence substituting in the above expression for  $u$ , and observing that  $f(D) \epsilon^{n\theta} = f(n) \epsilon^{n\theta}$ , we find

$$u_1 = A\epsilon^{a\theta} \{1 + \phi(a + r) \epsilon^{r\theta} + \phi(a + 2r) \phi(a + r) \epsilon^{2r\theta} + \dots\},$$

or, since  $\epsilon^\theta = x$ ,

$$u_1 = Ax^a \{1 + \phi(a + r) x^r + \phi(a + 2r) \phi(a + r) x^{2r} + \dots\};$$

and

$$\begin{aligned} u = & Ax^a \{1 + \phi(a+r)x^r + \phi(a+2r)\phi(a+r)x^{2r} + \dots\} \\ & + Bx^b \{1 + \phi(b+r)x^r + \phi(b+2r)\phi(b+r)x^{2r} + \dots\} \\ & + \dots, \end{aligned}$$

the solution sought.

Consider now the general equation

$$f_0(D)u + f_1(D)\epsilon^\theta u + \dots + f_n(D)\epsilon^{n\theta}u = 0.$$

Here we have, representing  $\frac{f_m(D)}{f_0(D)}$  by  $\phi_m(D)$ ,

$$\{1 + \phi_1(D)\epsilon^\theta + \dots + \phi_n(D)\epsilon^{n\theta}\}u = \{f_0(D)\}^{-1}0;$$

therefore

$$u = \{1 + \phi_1(D)\epsilon^\theta + \dots + \phi_n(D)\epsilon^{n\theta}\}^{-1} \{f_0(D)\}^{-1}0.$$

Here we have first to determine  $\{f_0(D)\}^{-1}0$ , then to determine the effect of the operation represented by

$$\{1 + \phi_1(D)\epsilon^\theta + \dots + \phi_n(D)\epsilon^{n\theta}\}^{-1}$$

upon this.

Now  $\{f_0(D)\}^{-1}0$  is given by the solution of a linear differential equation with constant coefficients, and will therefore be of the form

$$AP + BQ + CR + \dots,$$

$A, B, C, \dots$  being arbitrary constants, and  $P, Q, R, \dots$  functions of  $\theta$ .

Again, since

$$\begin{aligned} & \{1 + \phi_1(D)\epsilon^\theta + \dots + \phi_n(D)\epsilon^{n\theta}\}^{-1} \\ &= \frac{1}{1 + \phi_1(D)\epsilon^\theta + \dots + \phi_n(D)\epsilon^{n\theta}}, \end{aligned}$$

it may be shewn by a process of actual symbolical division,

attending to the laws of combination of symbols, that the expression may be expanded in the form

$$F_0(D) + F_1(D) \epsilon^\theta + F_2(D) \epsilon^{2\theta} + \dots$$

To determine the functions  $F_0(D)$ ,  $F_1(D)$ , ..... we may proceed as follows. From the equation

$$\begin{aligned} & \{1 + \phi_1(D) \epsilon^\theta + \dots + \phi_n(D) \epsilon^{n\theta}\}^{-1} \\ &= F_0(D) + F_1(D) \epsilon^\theta + F_2(D) \epsilon^{2\theta} + \dots \end{aligned}$$

we have

$$\begin{aligned} 1 &= \{1 + \phi_1(D) \epsilon^\theta + \dots + \phi_n(D) \epsilon^{n\theta}\} \{F_0(D) + F_1(D) \epsilon^\theta + F_2(D) \epsilon^{2\theta} + \dots\} \\ &= F_0(D) + \{F_1(D) + \phi_1(D) F_0(D-1)\} \epsilon^\theta + \dots (1). \end{aligned}$$

Hence  $F_0(D) = 1$ ,

$$F_1(D) + \phi_1(D) F_0(D-1) = 0;$$

therefore  $F_1(D) = -\phi_1(D) F_0(D-1)$ ,

and so on. Hence  $F_0(D)$ ,  $F_1(D)$ , ..... are determined in succession. The general law is as follows: the coefficient of  $\epsilon^{m\theta}$  in the second member of (1), when  $m$  is greater than 1, is

$$F_m(D) + \phi_1(D) F_{m-1}(D-1) + \phi_2(D) F_{m-2}(D-2) + \dots (2),$$

whence

$$F_m(D) = -\phi_1(D) F_{m-1}(D-1) - \phi_2(D) F_{m-2}(D-2) - \dots$$

By this formula the successive values of  $F_m(D)$  can be deduced from those of  $F_{m-1}(D)$ ,  $F_{m-2}(D)$ , .....

Combining the above results we obtain thus for  $u$  the expression

$$\begin{aligned} u &= \{1 + F_1(D) \epsilon^\theta + F_2(D) \epsilon^{2\theta} + \dots\} \{AP + BQ + \dots\} \\ &= A\{P + F_1(D) \epsilon^\theta P + F_2(D) \epsilon^{2\theta} P + \dots\} \\ &\quad + B\{Q + F_1(D) \epsilon^\theta Q + F_2(D) \epsilon^{2\theta} Q + \dots\} \\ &\quad + \dots \end{aligned}$$

Let us in applying this expression first suppose that the factors of  $f_0(D)$  are real and unequal, so that  $f_0(D)$  is of the

form  $(D - a)(D - b)(D - c) \dots$ . Further, let us suppose that no two of the quantities  $a, b, c, \dots$  differ by an integer.

Then  $\{f_0(D)\}^{-1} 0 = A\epsilon^{a\theta} + B\epsilon^{b\theta} + \dots,$

whence we may assume

$$P = \epsilon^{a\theta}, \quad Q = \epsilon^{b\theta}, \dots$$

Thus the expression for  $u$  becomes

$$\begin{aligned} & A\{\epsilon^{a\theta} + F_1(D)\epsilon^{(a+1)\theta} + F_2(D)\epsilon^{(a+2)\theta} + \dots\} \\ & + B\{\epsilon^{b\theta} + F_1(D)\epsilon^{(b+1)\theta} + F_2(D)\epsilon^{(b+2)\theta} + \dots\} \\ & + \dots; \end{aligned}$$

or, since  $F(D)\epsilon^{m\theta} = F(m)\epsilon^{m\theta},$

$$\begin{aligned} u &= A\{\epsilon^{a\theta} + F_1(a+1)\epsilon^{(a+1)\theta} + F_2(a+2)\epsilon^{(a+2)\theta} + \dots\} \\ & + B\{\epsilon^{b\theta} + F_1(b+1)\epsilon^{(b+1)\theta} + F_2(b+2)\epsilon^{(b+2)\theta} + \dots\} \\ & + \dots \end{aligned}$$

Hence, replacing  $\epsilon^\theta$  by  $x$ ,

$$\begin{aligned} u &= A\{x^a + F_1(a+1)x^{a+1} + F_2(a+2)x^{a+2} + \dots\} \\ & + B\{x^b + F_1(b+1)x^{b+1} + F_2(b+2)x^{b+2} + \dots\} \\ & + \dots \end{aligned}$$

In (2) replace in like manner  $D$  by  $a+i$  and we have, putting  $i$  for  $m$ ,

$$\begin{aligned} & F_i(a+i) + \phi_1(a+i)F_{i-1}(a+i-1) \\ & + \phi_2(a+i)F_{i-2}(a+i-2) + \dots = 0, \end{aligned}$$

or, if  $F_i(a+i)$  be represented by  $u_{a+i}$ ,

$$u_{a+i} + \phi_1(a+i)u_{a+i-1} + \phi_2(a+i)u_{a+i-2} + \dots = 0.$$

Put  $m$  for  $a+i$ , thus

$$u_m + \phi_1(m)u_{m-1} + \phi_2(m)u_{m-2} + \dots = 0.$$

This agrees with the law established in [there is no reference in the manuscript, but the law intended appears to be that given in Chap. XVII. Art. 9.]

Secondly, suppose that  $r$  of the factors of  $f_0(D)$  are equal and of the form  $D - \alpha$ .

Then  $\{f_0(D)\}^{-1} 0$  contains a term of the form

$$\epsilon^{a\theta} (c_0 + c_1\theta + c_2\theta^2 + \dots + c_{r-1}\theta^{r-1}).$$

Hence the corresponding portion of  $u$  is of the form

$$\begin{aligned} & \left\{ 1 + F_1(D) \epsilon^\theta + F_2(D) \epsilon^{2\theta} + \dots \right\} \epsilon^{a\theta} (c_0 + c_1\theta + \dots + c_{r-1}\theta^{r-1}) \\ &= \left\{ \epsilon^{a\theta} + \epsilon^{(a+1)\theta} F_1'(D + \alpha + 1) + \epsilon^{(a+2)\theta} F_2'(D + \alpha + 2) + \dots \right\} v \dots (3) \end{aligned}$$

where  $v$  stands for  $c_0 + c_1\theta + c_2\theta^2 + \dots + c_{r-1}\theta^{r-1}$ .

Now  $F_i(D + \alpha + i) v$

$$= \left\{ F_i(\alpha + 1) + F_i'(\alpha + 1) D + F_i''(\alpha + 1) \frac{D^2}{1 \cdot 2} + \dots \right\} v,$$

which on performing the differentiations becomes a polynomial of the form

$$A_0 + A_1\theta + \dots + A_{r-1}\theta^{r-1}.$$

We see thus that (3) will assume the form of a series of terms  $\epsilon^{a\theta}$ ,  $\epsilon^{(a+1)\theta}$ ,  $\dots$  each multiplied by a polynomial of the  $(r-1)^{\text{th}}$  degree in  $\theta$ . Or arranging the terms otherwise it will consist of a series of terms of the form

$$B_0 + B_1\theta + \dots + B_{r-1}\theta^{r-1},$$

in which  $B_0, B_1, \dots, B_{r-1}$  are series involving  $\epsilon^{a\theta}$ ,  $\epsilon^{(a+1)\theta}$ ,  $\epsilon^{(a+2)\theta}$ ,  $\dots$ . Or lastly, changing  $\epsilon^\theta$  to  $x$ , the portion of  $u$  in question is of the form

$$B_0 + B_1(\log x) + \dots + B_{r-1}(\log x)^{r-1},$$

$B_0, B_1, \dots, B_{r-1}$  being polynomials in each of which the lowest power of  $x$  is  $x^a$ , and the successive powers increase by unity.

This establishes the assumption in [there is no reference in the manuscript; probably Chap. XVII. Art. 10 is to be supplied.]

Thirdly, let  $f_0(D)$  contain  $r$  factors  $D - a_1, D - a_2, \dots, D - a_r$  in which  $a_1, a_2, \dots, a_r$  differ from each other by integers, together with other factors.

The portion of  $u$  corresponding to the factor  $D - a_i$  will be

$$\{1 + F_1(D) \epsilon^\theta + F_2(D) \epsilon^{2\theta} + \dots\} A \epsilon^{a_i \theta},$$

in which

$$F_m(D) \epsilon^{m\theta} = - \left\{ \phi_1(D) \epsilon^\theta F_{m-1}(D) \epsilon^{(m-1)\theta} + \phi_2(D) \epsilon^{2\theta} F_{m-2}(D) \epsilon^{(m-2)\theta} + \dots \right\}.$$

Thus  $F_m(D) \epsilon^{m\theta}$  consists of terms of the form

$$\phi_i(D) \epsilon^{i\theta} F_{m-i}(D) \epsilon^{(m-i)\theta},$$

$i$  being one of the numbers  $1, 2, \dots, n$ . Hence  $F_{m-i}(D) \epsilon^{(m-i)\theta}$  will consist of terms of the form

$$\phi_j(D) \epsilon^{j\theta} F_{m-i-j}(D) \epsilon^{(m-i-j)\theta},$$

$j$  being one of the numbers  $1, 2, \dots, n$ . Continuing this until  $i + j + k + \dots = m$ , we see that  $F_m(D) \epsilon^{m\theta}$  will ultimately consist of terms of the form

$$\phi_i(D) \epsilon^{i\theta} \phi_j(D) \epsilon^{j\theta} \phi_k(D) \epsilon^{k\theta} \dots,$$

$i, j, k, \dots$  receiving arbitrarily any of the values  $1, 2, \dots, n$ , and  $i + j + k + \dots$  being equal to  $m$ .

Thus the portion of  $u$  derived from  $A \epsilon^{a_i \theta}$  will consist of all possible terms of the form

$$\begin{aligned} & A \phi_i(D) \epsilon^{i\theta} \phi_j(D) \epsilon^{j\theta} \phi_k(D) \epsilon^{k\theta} \dots (\epsilon^{a_i \theta}) \\ &= A \phi_i(D) \phi_j(D - i) \phi_k(D - i - j) \dots \epsilon^{(m+a_i)\theta} \\ &= \frac{A f_i(D) f_j(D - i) f_k(D - i - j) \dots}{f_0(D) f_0(D - i) f_0(D - i - j) \dots} \epsilon^{(m+a_i)\theta}. \end{aligned}$$

Let  $i = \alpha$ ,  $i + j = \beta$ , .....  $i + j + k + \dots$  excluding the last term  $= \mu$ ; and let the symbolical numerator which involves only direct functions be represented by  $f(D)$ , and we have

$$\frac{Af(D)}{f_0(D)f_0(D-\alpha)f_0(D-\beta)\dots f_0(D-\mu)} \epsilon^{(m+a_i)\theta},$$

in which  $\alpha, \beta, \dots, \mu, m$  are integers ascending by differences not exceeding  $n$ .

[A few lines of the manuscript here are obscure, and I venture to express in other words the idea which seems to be involved.

Let  $D - \alpha_s$  denote one factor of  $f_0(D)$ , then the corresponding factors in the denominator of

$$\frac{Af(D) \epsilon^{(m+a_i)\theta}}{f_0(D)f_0(D-\alpha)f_0(D-\beta)\dots f_0(D-\mu)} \dots\dots\dots (4),$$

are  $(D - \alpha_s)(D - \alpha_s - \alpha) \dots\dots (D - \alpha_s - \mu) \dots\dots\dots (5).$

Now if  $\alpha_s$  is not greater than  $\alpha_i$ , then  $\alpha_s + \mu$  is less than  $\alpha_i + m$ ; hence no factor in the expression (5) can be identical with  $D - m - \alpha_i$ . But if  $\alpha_s$  is greater than  $\alpha_i$ , then *one* factor in the expression (5) may be identical with  $D - m - \alpha_i$ .

Hence it follows that the denominator of the expression (4) *may* contain  $D - m - \alpha_i$  to the power  $r - 1$ , but not to a higher power.]

And, since

$$\begin{aligned} & (D - m - \alpha_i)^{-(r-1)} \epsilon^{(m+a_i)\theta} \\ &= \epsilon^{(m+a_i)\theta} \left\{ c_0 + c_1\theta + \dots + c_{r-2}\theta^{r-2} + \frac{\theta^{r-1}}{r-1} \right\}, \end{aligned}$$

we see that  $u$  will contain  $r$  sets of terms together of the form

$$A + B(\log x) + C(\log x)^2 + \dots + K(\log x)^{r-1},$$

$A, B, C, \dots$  being polynomials in  $x$ .

This establishes the rule in [there is no reference in the manuscript; probably Chap. xvii. Art. 10 is to be supplied.]

[There is no hint in the manuscript as to the position which Article 2 was intended to occupy; and the reasoning does not seem fully developed.]

2. PROP. The solution of the equation

$$f_0(D)u + f_1(D)\epsilon^\theta u + \dots + f_n(D)\epsilon^{n\theta}u = 0$$

being expressed in the form

$$\{1 + F_1(D)\epsilon^\theta + F_2(D)\epsilon^{2\theta} + \dots + \{f_0(D)\}^{-1}0,$$

it is not necessary to introduce new constants in interpreting  $F_1(D)$ , ....; it suffices to interpret particularly if only uniformly and consistently.

For let

$$\{f_0(D)\}^{-1}0 = AP + BQ + \dots;$$

and in interpreting

$$F_m(D)\epsilon^{m\theta}(AP + BQ + \dots)$$

let a new constant be introduced which was not in the interpretation of

$$F_{m-1}(D)\epsilon^{(m-1)\theta}(AP + BQ + \dots).$$

$$\begin{aligned} \text{Now} \quad F_m'(D)\epsilon_m^\theta + \phi_1(D)\epsilon^\theta F_{m-1}(D)\epsilon^{(m-1)\theta} \\ + \phi_2(D)\epsilon^{2\theta} F_{m-2}(D)\epsilon^{(m-2)\theta} + \dots = 0, \end{aligned}$$

therefore

$$\begin{aligned} F_m'(D)\epsilon^{m\theta} &= -\phi_1(D)\epsilon^\theta F_{m-1}(D)\epsilon^{(m-1)\theta} - \dots \\ &= -\{f_0(D)\}^{-1}\{f_1(D)\epsilon^\theta F_{m-1}(D)\epsilon^{(m-1)\theta} + \dots\}, \end{aligned}$$

hence the new constant comes from  $\{f_0(D)\}^{-1}0$ , and the term containing it must be  $A'P$ , or  $B'Q$ , ...., where  $A'$ ,  $B'$  .... are constants. Suppose it  $A'P$ ;

then as derived from this,

$$\begin{aligned} F_{m+1}(D)\epsilon^{(m+1)\theta}\{f_0(D)\}^{-1}0 &= -\phi_1(D)\epsilon^\theta A'P, \\ F_{m+2}(D)\epsilon^{(m+2)\theta}\{f_0(D)\}^{-1}0 &= -\phi_1(D)\epsilon^\theta F_{m+1}(D)\epsilon^{(m+1)\theta}A'P \\ &\quad - \phi_2(D)\epsilon^{2\theta}F_m(D)\epsilon^{m\theta}A'P. \end{aligned}$$

$$\begin{aligned} \text{Thus} \quad F_{(m+i)}(D) \epsilon^{(m+i)\theta} &= -\phi_1(D) \epsilon^\theta F_{m+i-1} \epsilon^{(m+i-1)\theta} \\ &\quad - \phi_2(D) \epsilon^\theta F_{m+i-2} \epsilon^{(m+i-2)\theta} \\ &\quad - \dots \end{aligned}$$

The law of derivation is exactly the same as in the derivation of  $F_i(D) \epsilon^{i\theta}$  from  $F_{i-1}(D) \epsilon^{(i-1)\theta}$ , .....

[Art. 3 seems intended for a reconstruction on an extended scale of part of Chapter XVII. Art. 3.]

3. We proceed to consider more fully the theory of the binomial equation

$$u + \phi(D) \epsilon^{r\theta} u = U.$$

Now the possibility of solving the equation depends upon the nature of the symbolic function  $\phi(D)$ . It is perhaps the most general account of the present state of the theory to say that there exist certain *primary* forms of this function which render the equation solvable, and that to each of these primary forms an infinite number of the forms are reducible by general theorems of transformation. As these theorems admit of a statement which is independent of the form of the function  $\phi(D)$ , we shall establish them first.

PROP. II. *The function  $\phi(D)$  in the equation*

$$u + \phi(D) \epsilon^{r\theta} u = U$$

*can without otherwise changing the first member of that equation be 1st affected with any constant factor, or 2ndly converted into  $\phi(D+a)$ , or 3rdly converted into  $\{\phi(-D)\}^{-1}$ .*

First. Let  $U = f(\epsilon^\theta)$ , and in the equation

$$u + \phi(D) \epsilon^{r\theta} u = f(\epsilon^\theta),$$

let  $\epsilon^\theta = a^{\frac{1}{r}} \epsilon^{\theta'}$ . Then  $\frac{d}{d\theta} = \frac{d}{d\theta'}$ , and the equation becomes

$$u + a\phi(D) \epsilon^{r\theta'} u = f(a^{\frac{1}{r}} \epsilon^{\theta'}),$$

in which  $D = \frac{d}{d\theta'}$ . Thus  $\phi(D)$  has been affected by a constant factor  $\alpha$ .

Secondly. In the same system let  $u = \epsilon^{a\theta} v$ . Then

$$\epsilon^{a\theta} v + \phi(D) \epsilon^{(a+r)\theta} v = f(\epsilon^\theta),$$

or

$$\epsilon^{a\theta} v + \epsilon^{a\theta} \phi(D + \alpha) \epsilon^{r\theta} v = f(\epsilon^\theta),$$

therefore

$$v + \phi(D + \alpha) \epsilon^{r\theta} v = \epsilon^{-a\theta} f(\epsilon^\theta).$$

Here  $\phi(D)$  has been changed into  $\phi(D + \alpha)$ .

The result of this transformation may be conveniently expressed by the following theorem.

*The equation*

$$u + \phi(D) \epsilon^{r\theta} u = U$$

*will be converted into*

$$v + \phi(D + \alpha) \epsilon^{r\theta} v = V$$

*by the relations*

$$u = \epsilon^{a\theta} v, \quad U = \epsilon^{a\theta} V.$$

Thirdly. In the same equation let  $\theta = -\theta'$ ; then

$$\frac{d}{d\theta} = -\frac{d}{d\theta'},$$

and we have

$$u + \phi(-D) \epsilon^{-r\theta'} u = f(\epsilon^{-\theta'}),$$

in which

$$D = \frac{d}{d\theta'}. \quad \text{Hence}$$

$$u + \epsilon^{-r\theta'} \phi\{-(D - r)\} u = f(\epsilon^{-\theta'});$$

therefore

$$\epsilon^{r\theta'} u + \phi(r - D) u = \epsilon^{r\theta'} f(\epsilon^{-\theta'}),$$

whence  $u + \{\phi(r - D)\}^{-1} \epsilon^{r\theta'} u = \{\phi(r - D)\}^{-1} \epsilon^{r\theta'} f(\epsilon^{-\theta'})$ .

In this equation let  $u = \epsilon^{r\theta'} v$ . Then by the last theorem,

$$v + \{\phi(-D)\}^{-1} \epsilon^{r\theta'} v = \{\phi(-D)\}^{-1} f(\epsilon^{-\theta'}).$$

Thus

$$u + \phi(D) \epsilon^{r\theta} u = f(\epsilon^\theta)$$

is converted into

$$v + \{\phi(-D)\}^{-1} \epsilon^{r\theta'} v = \{\phi(-D)\}^{-1} f(\epsilon^{-\theta'}),$$

in which  $D = \frac{d}{d\theta'}$ , by assuming

$$\theta = -\theta', \quad u = \epsilon^{r\theta'} v.$$

The above transformations leave the index  $r$  in the first member unchanged. If however we assume  $\theta = \frac{\theta'}{a}$ , whence  $\frac{d}{d\theta} = a \frac{d}{d\theta'}$ , we should have

$$u + \phi(aD) \epsilon^{\frac{r\theta'}{a}} = f(\epsilon^{\frac{\theta'}{a}}).$$

By combining this with the previous results we see that it is possible to convert  $\phi(D)$  into  $\phi(aD + b)$ , and into  $\{\phi(aD + b)\}^{-1}$ .

But the most important transformation of the function  $\phi(D)$  is that which is established in the following proposition.

[The proposition referred to is Prop. III. of Chap. XVII. Art. 3.]

[Article 4 was intended to follow the words "or subsequently in the derivation of  $u$ " in Chap. XVII. Art. 4.]

4. It becomes therefore important to establish rules for the treatment of the constants which in these different ways arise.

Now the entire process of solution consists of three stages, namely :

1st, the determination of  $V$  by the equation

$$V = P_r \frac{\psi(D)}{\phi(D)} U.$$

2ndly, the solution of the transformed equation

$$v + \psi(D) \epsilon^{r\theta} v = V,$$

3rdly, the determination of  $u$  by the relation

$$u = P_r \frac{\phi(D)}{\psi(D)} v.$$

Let us consider these separately, supposing  $\phi(D)$  to contain a single factor  $\frac{D+a}{D+b}$  which is made to disappear in the generation of  $\psi(D)$ , so that  $a$  and  $b$  differ by a multiple of  $r$ . Thus the given equation is of the form

$$u - \frac{D+a}{D+b} \psi(D) \epsilon^{r\theta} u = U \dots \dots \dots (6).$$

The transformed equation is of the form

$$v - \psi(D) \epsilon^{r\theta} v = V,$$

in which  $u = P_r \frac{D+a}{D+b} v, \quad V = P_r \frac{D+b}{D+a} U.$

First, suppose  $a - b = nr$ , where  $n$  is positive.

Thus

$$u = (D+a) (D+a-r) \dots (D+a-nr+r) v,$$

$$V = \left\{ (D+a) (D+a-r) \dots (D+a-nr+r) \right\}^{-1} U.$$

Hence

$$\begin{aligned} u &= (D+a) \dots (D+a-nr+r) \{1-\psi(D)\epsilon^\theta\}^{-1} V \\ &= (D+a) \dots (D+a-nr+r) \{1-\psi(D)\epsilon^{r\theta}\}^{-1} \left\{ U_1 + C_1 \epsilon^{-a\theta} \right. \\ &\quad \left. + C_2 \epsilon^{-(a-r)\theta} + \dots + C_n \epsilon^{-(a-nr+r)\theta} \right\} \dots (7), \end{aligned}$$

where  $U_1$  is a particular value of

$$\left\{ (D+a) \dots (D+a-nr+r) \right\}^{-1} U.$$

The part containing the constants will consist of terms of the form

$$\begin{aligned} &(D+a) \dots (D+a-nr+r) \{1-\psi(D)\epsilon^{r\theta}\}^{-1} C \epsilon^{-(a-ir)\theta} \\ &= (D+a) (D+a-r) \dots (D+a-nr+r) \left\{ 1 + \psi(D)\epsilon^{r\theta} \right. \\ &\quad \left. + \psi(D)\epsilon^{r\theta} \psi(D)\epsilon^{r\theta} + \dots \right\} C \epsilon^{-(a-ir)\theta} \\ &= C (D+a) (D+a-r) \dots (D+a-nr+r) \left\{ \epsilon^{-(a-ir)\theta} \right. \\ &\quad \left. + \psi(D)\epsilon^{-(a-ir-r)\theta} + \psi(D)\psi(D-r)\epsilon^{-(a-ir-2r)\theta} + \dots \right\}. \end{aligned}$$

Now all these terms vanish up to the one containing  $\epsilon^{-(a-nr)\theta}$ ; therefore we have to perform the operation

$C (D+a) (D+a-r) \dots (D+a-nr+r)$  on

$$\begin{aligned} &\left\{ \psi(D)\psi(D-r) \dots \psi(D-jr) \epsilon^{-(a-nr)\theta} \right. \\ &\quad \left. + \psi(D)\psi(D-r) \dots \psi(D-jr-r) \epsilon^{-(a-nr-r)\theta} + \dots \right\}, \end{aligned}$$

where  $j = n - i - 1$ ; that is, we have to perform the operation

$C (D+a) (D+a-r) \dots (D+a-nr+r)$  on

$$\begin{aligned} &\left\{ \psi(D)\psi(D-r) \dots \psi(D-jr) \epsilon^{-(a-nr)\theta} \right. \\ &\quad \left. + \psi(D)\epsilon^\theta \psi(D) \dots \psi(D-jr) \epsilon^{-(a-nr)\theta} + \dots \right\}. \end{aligned}$$

$$\begin{aligned}
\text{Now } & \psi(D) \psi(D-r) \dots \psi(D-jr) \epsilon^{-(a-nr)\theta} \\
&= \psi(nr-a) \psi(nr-r-a) \dots \psi(nr-jr-a) \epsilon^{-(a-nr)\theta} \\
&= B\epsilon^{-(a-nr)\theta};
\end{aligned}$$

therefore we obtain

$$\begin{aligned}
BC(D+a) \dots (D+a-nr+r) & \left\{ \epsilon^{-(a-nr)\theta} + \psi(D) \epsilon^\theta \epsilon^{-(a-nr)\theta} + \dots \right\} \\
&= BC(D+a) \dots (D+a-nr+r) \left\{ 1 + \psi(D) \epsilon^\theta \right. \\
& \quad \left. + \psi(D) \epsilon^\theta \psi(D) \epsilon^\theta + \dots \right\} \epsilon^{-(a-nr)\theta}.
\end{aligned}$$

Thus this expression is the same in form for all values of  $i$ . Therefore all the terms containing an arbitrary constant in (7) are equivalent to only one term.

Secondly, suppose  $a-b = -nr$ .

$$\text{Then } u = \left\{ (D+b) (D+b-r) \dots (D+b-nr+r) \right\}^{-1} v,$$

$$V = (D+b) (D+b-r) \dots (D+b-nr+r) U.$$

Here there are no constants in  $V$ . But  $u$  contains  $n$  arbitrary constants not in  $v$ , and as there is no subsequent process in the method for destroying these or reducing them to mutual dependence, it is necessary that the relations connecting them should be sought by comparing the solution with that given by the method of development in series.

NOTE. It would be better to reduce (6) to the form

$$u - \frac{D}{D-a} \psi(D) \epsilon^\theta u = U$$

before the demonstration.

[Article 5 was intended to follow Chap. XVII. Art. 7.

There is a memoir by Professor Boole on the subject of this Article, entitled *On the Differential Equations which determine the form of the Roots of Algebraic Equations*. The memoir occupies pages 733—755 of the *Philosophical Transactions* for 1864.]

5. If we agree to regard as *primary* those forms of binomial equations which are integrable but not through any reduction effected by the Propositions of Art. 3, and to which equations through the application of those propositions other equations are reducible and so made integrable, it becomes very important to enquire what these primary integrable forms are. It does not appear at present possible to give a general answer to this question, but so far as is known, such forms if belonging to differential equations of a degree higher than the first stand in a remarkable connexion with the theory of algebraical equations. By the study of this theory Mr Harley was led to the conclusion that  $y$  defined as an implicit function of  $x$  by the algebraical equation

$$y^n - ny + (n-1)x = 0 \dots \dots \dots (8),$$

$n$  being greater than 2, satisfies the binomial differential equation

$$y - \frac{\left(D - \frac{2n-1}{n}\right)\left(D - \frac{3n-2}{n}\right) \dots \left(D - \frac{n^2-n+1}{n}\right)}{D(D-1) \dots (D-n+2)} \epsilon^{(n-1)\theta} y = 0,$$

in which  $\epsilon^\theta = x$ . In this expression the factors of the numerator are equidifferent, as of the denominator, their common difference being  $\frac{n-1}{n}$ , but the equation is not resolvable by Propositions II. and III. into forms, the integrability which had before been recognised.

The above result first reached by induction was confirmed by Mr Cayley by the aid of Lagrange's theorem.

To the form (8) all algebraic equations of the third, fourth, and fifth degrees are known to be reducible.

Mr Harley has subsequently found that  $y$  considered as a function of  $x$  defined implicitly by the equation

$$y^n - ny^{n-1} + (n-1)x = 0$$

satisfies the symbolical differential equation

$$\begin{aligned} n^{n-1}[(n-1)D]^{n-1}y - (n-1)(nD-n-1)[nD-2]^{n-2}\epsilon^\theta y \\ = [n-1]^{n-1}\epsilon^\theta \end{aligned}$$

the factorial notation according to which

$$[m]^n = m(m-1)(m-2) \dots (m-n+1)$$

being here adopted.

These results are implicitly involved in a more general theorem which I shall now demonstrate.

**THEOREM.** *If  $y_1, y_2, \dots, y_n$  are the  $n$  roots of the algebraic equation*

$$y^n - ay^{n-1} + 1 = 0,$$

*and if the  $m^{\text{th}}$  power of any one of these roots be represented by  $u$ , and  $\log a$  by  $\theta$ , then  $u$  as a function of  $\theta$  satisfies the differential equation*

$$u - \frac{\left[ \frac{n-1}{n} D + \frac{m}{n} - 1 \right]^{n-1} \left( \frac{D}{n} - \frac{m}{n} - 1 \right)}{[D]^n} e^{n\theta} u = 0.$$

*And the complete integral of the above differential equation will be*

$$u = C_1 y_1^m + C_2 y_2^m + \dots + C_n y_n^m.$$

Let  $y^n = z$ , then the given equation may be expressed in the form

$$z = b + az^{\frac{n-1}{n}},$$

in which  $b = -1$ . Hence, by Lagrange's theorem,

$$\begin{aligned} u = z^{\frac{m}{n}} &= b^{\frac{m}{n}} + ab^{\frac{n-1}{n}} \frac{d}{db} b^{\frac{m}{n}} \\ &+ \frac{1}{1 \cdot 2} \frac{d}{db} \left\{ \left( ab^{\frac{n-1}{n}} \right)^2 \frac{d}{db} b^{\frac{m}{n}} \right\} + \&c., \end{aligned}$$

the general term being

$$\frac{1}{1 \cdot 2 \dots r} \left( \frac{d}{db} \right)^{r-1} \left\{ \left( ab^{\frac{n-1}{n}} \right)^r \frac{d}{db} b^{\frac{m}{n}} \right\},$$

which on effecting the differentiations and adopting the factorial notation becomes

$$\frac{m \left[ \frac{m + (n-1)r}{n} - 1 \right]^{r-1} b^{\frac{m-r}{n}}}{n [r]^r} a^r,$$

and this expression will be found to represent the first term as well as the others of Lagrange's expansion provided that we interpret the form

$$[p]^0 \text{ by } 1, \text{ and } [p]^{-1} \text{ by } \frac{1}{1+p}.$$

Further, the above general development includes the  $n$  particular developments of  $u$  or  $y^{\frac{m}{n}}$  arising from the giving to  $b^{\frac{1}{n}}$  its  $n$  particular algebraic values. In this way it represents the  $m^{\text{th}}$  power of each of the  $n$  roots  $y_1, y_2, \dots, y_n$  in succession.

Now representing the above general term by  $u_r a^r$ , we shall have

$$u_r = \frac{m \left[ \frac{m + (n-1)r}{n} - 1 \right]^{r-1} b^{\frac{m-r}{n}}}{n [r]^r},$$

$$u_{r-n} = \frac{m \left[ \frac{m + (n-1)r}{n} - n \right]^{r-n-1} b^{\frac{m-r}{n} + 1}}{n [r-n]^{r-n}}.$$

Therefore, after reduction and replacing  $b$  by  $-1$ ,

$$\frac{u_r}{u_{r-n}} = \frac{\left[ \frac{m + (n-1)r}{n} - 1 \right]^{n-1} \left( \frac{r}{n} - \frac{m}{n} - 1 \right)}{[r]^n} \dots (9).$$

It follows therefore that the complete series of which the general term is  $u_r a^r$  will if represented by  $u$  satisfy the differential equation

$$u - \frac{\left[ \frac{n-1}{n} D + \frac{m}{n} - 1 \right]^{n-1} \left( \frac{D}{n} - \frac{m}{n} - 1 \right)}{[D]^n} \epsilon^{n\theta} u = 0 \dots (I).$$

If we integrate the equation in a series (Chap. XVII. Art. 9), the initial terms of the value of  $u$  will be

$$C_0 + C_1 a + C_2 a^2 \dots + C_{n-1} a^{n-1},$$

the succeeding terms being formed from these by the law (9). Hence, if the arbitrary constants  $C_0 C_1 \dots C_{n-1}$  be so determined as to make the above initial terms agree with the first  $n$  terms of the Lagrangean expansion in any of its particular forms, the succeeding terms will also agree, and the Lagrangean expansion will thus become a particular integral of the equation (I). The aggregate of such particular integrals, each affected by an arbitrary constant, will therefore also be an integral of the differential equation, and will, in fact, constitute its general integral, subject to exception only in the case in which for a particular value of  $m$  the integrals  $y_1^m, y_2^m, \dots, y_n^m$  cease to be independent.

For instance, if  $m = -1$ , and we reduce the equation to the form

$$(y^{-1})^n - \alpha y^{-1} + 1 = 0,$$

it is seen that except when  $n = 2$ , we have

$$y_1^{-1} + y_2^{-1} \dots + y_n^{-1} = 0.$$

Here then the solution

$$u = C_1 y_1^m + C_2 y_2^m \dots + C_n y_n^m \dots \dots \dots (10)$$

ceases to be general for it becomes

$$u = (C_1 - C_n) y_1^{-1} + (C_2 - C_n) y_2^{-1} \dots + (C_{n-1} - C_n) y_{n-1}^{-1},$$

and virtually involves but  $n - 1$  arbitrary constants.

If, however, we give to the integral the form

$$u = C_1 y_1^m + C_2 y_2^m \dots + C_{n-1} y_{n-1}^m + C_n \frac{y_1^m + y_2^m \dots + y_n^m}{m + 1},$$

the last term of which becomes a vanishing fraction when  $m = -1$ , we find for the general value of  $u$  in this case

$$u = C_1 y_1^{-1} + C_2 y_2^{-1} \dots + C_{n-1} y_{n-1}^{-1} \\ + C_n (y_1^{-1} \log y_1 + y_2^{-1} \log y_2 \dots + y_n^{-1} \log y_n),$$

and in this way we may proceed in failing cases generally.

Lastly, it may be observed that in certain cases the differential equation (I) admits of reduction to an order lower by unity than its own. And in particular this happens in the failing cases above noticed. Thus, if in (I) we make  $m = -1$  the equation will be expressible in the form

$$D(D-1) \dots (D-n+1) u \\ - \frac{1}{n} \left[ \frac{n-1}{n} D - \frac{1}{n} - 1 \right]^{n-1} (D-n+1) \epsilon^{n\theta} u = 0,$$

whence, operating on both members with  $(D-n+1)^{-1}$ , we have

$$[D]^{n-1} u - \frac{1}{n} \left[ \frac{n-1}{n} D - \frac{1}{n} - 1 \right]^{n-1} \epsilon^{n\theta} u = C \epsilon^{(n-1)\theta}.$$

The general integral of this equation will be expressed by (10) provided that a proper relation be established between  $C$  and the constants  $C_1, C_2, \dots, C_n$ . If we choose to determine  $C$  so as to give to the integral the particular form  $y^{-1}$ , we shall find on substituting for  $u$  its Lagrangean development making  $m = -1$ ,  $b = -1$ , and calculating the coefficient of  $a^{n-1}$  or  $\epsilon^{(n-1)\theta}$  in the first member of the differential,

$$C = \frac{[n-3]^{n-2}}{n}.$$

Hence, if  $n$  be greater than 2, we have  $C = 0$ . It follows therefore that if  $n$  be greater than 2, the equation

$$[D]^{n-1} u - \frac{1}{n} \left[ \frac{n-1}{n} D - \frac{1}{n} - 1 \right]^{n-1} \epsilon^{n\theta} u = 0 \dots \dots (II),$$

in which  $\epsilon^\theta = a$  has for its general integral

$$u = C_1 y_1^{-1} + C_2 y_2^{-1} \dots + C_{n-1} y_{n-1}^{-1},$$

$y_1, y_2, \dots, y_{n-1}$  being any  $n - 1$  roots of the equation

$$y^n - a y^{n-1} + 1 = 0.$$

It may be useful to notice the forms which the above results assume when  $\theta$  is changed into  $-\theta$ , and therefore  $D$  into  $-D$ ; see Art. 3.

It will be found that (I) becomes

$$u - \frac{[D - 1]^n}{\left[ \frac{n-1}{n} D - \frac{m}{n} \right]^{n-1} \left( \frac{D}{n} + \frac{m}{n} \right)} \epsilon^{n\theta} u = 0 \dots \dots (III),$$

of which the integral is therefore

$$u = C_1 y_1^m + C_2 y_2^m \dots + C_n y_n^m,$$

$y_1, y_2, \dots, y_n$  being the roots of the equation

$$y^n - \frac{1}{a} y^{n-1} + 1 = 0 \dots \dots \dots (11);$$

and  $\log a$  being denoted by  $\theta$ ;

while as the equivalent of (II) we have

$$u - n \frac{[D - 2]^{n-1}}{\left[ \frac{n-1}{n} D + \frac{1}{n} \right]^{n-1}} \epsilon^{n\theta} u = 0 \dots \dots \dots (IV),$$

of which, supposing  $n$  greater than 2, the integral is

$$u = C_1 y_1^{-1} + C_2 y_2^{-1} \dots + C_{n-1} y_{n-1}^{-1},$$

$y_1, y_2, \dots, y_{n-1}$  being any  $n - 1$  roots of the same algebraic equation.

Mr Harley's results may readily be deduced from the above. Thus it will be found that the equation (11) reduces to

$$t^n - nt + (n-1)x = 0$$

if we make

$$y^{-1} = (n-1)^{-\frac{1}{n}} x^{-\frac{1}{n}} t, \quad a = \frac{(n-1)^{\frac{n-1}{n}} x^{\frac{n-1}{n}}}{n}.$$

Hence, making  $x = \epsilon^{\theta'}$  and representing  $\frac{d}{d\theta'}$  by  $D'$ , we have for the transformation of (IV)

$$\epsilon^{\theta} = \frac{(n-1)^{\frac{n-1}{n}}}{n} \epsilon^{\frac{n-1}{n} \theta'},$$

$$D = \frac{n}{n-1} D',$$

$$u = (n-1)^{-\frac{1}{n}} \epsilon^{\frac{-\theta'}{n}} t.$$

Substituting and multiplying the result by  $\epsilon^{\frac{\theta'}{n}}$ , we find

$$t - \left(\frac{n-1}{n}\right)^{n-1} \frac{\left[\frac{n}{n-1} D' - \frac{2n-1}{n-1}\right]^{n-1}}{[D']^{n-1}} \epsilon^{(n-1)\theta} t = 0,$$

which is Mr Harley's first equation.

If in (I) and (III) we make  $1 - \frac{m}{n} = \alpha$ , whence  $m = n - n\alpha$ , and at the same time change  $a$  into  $ab^{-\frac{1}{n}}$ , and  $y$  into  $yb^{-\frac{1}{n}}$ , we shall obtain the following somewhat more general statement of their united import.

*The differential equations*

$$u - \frac{1}{b} \frac{\left[ \frac{n-1}{n} D - \alpha \right]^{n-1} \left( \frac{D}{n} + \alpha - 2 \right)}{[D]^n} \epsilon^{n\theta} u = 0,$$

$$u - b \frac{[D-1]^n}{\left[ \frac{n-1}{n} D + \alpha - 1 \right]^{n-1} \left( \frac{D}{n} - \alpha + 1 \right)} \epsilon^{n\theta} u = 0,$$

*are both satisfied by the general integral*

$$u = C_1 y_1^{n-n\alpha} + C_2 y_2^{n-n\alpha} \dots + C_n y_n^{n-n\alpha},$$

*when  $y_1, y_2, \dots, y_n$  are the roots of the algebraic equation*

$$y^n - \alpha y^{n-1} + b = 0,$$

*provided that for the first equation  $\alpha = \epsilon^\theta$ , and for the second  $\alpha = \epsilon^{-\theta}$ .*

If  $n = 2$ , the above equations assume the forms

$$u - \frac{1}{b} \frac{\left( \frac{D}{2} - \alpha \right) \left( \frac{D}{2} + \alpha - 2 \right)}{D(D-1)} \epsilon^{2\theta} u = 0,$$

$$u - b \frac{(D-1)(D-2)}{\frac{D^2}{4} - (\alpha-1)^2} \epsilon^{2\theta} u = 0.$$

6. [The two principal papers by Mr Harley on the differential equations exhibited on page 190 are the following :

(1) On the Theory of the Transcendental Solution of Algebraic Equations, *Quarterly Journal of Mathematics*, Vol. v. pages 337...360.

(2) On a certain class of Linear Differential Equations. *Manchester Memoirs. Third Series.* Vol. II. pages 232...245.

In a letter bearing date January 13, 1864, Professor Boole pointed out to Mr Harley that his second equation might also be deduced from the general theorem discussed in Art. 5. Employing the above notation the deduction may be presented in the following form.

The equation (11) will reduce to

$$t^n - nt^{n-1} + (n-1)x = 0,$$

if we make

$$y = (n-1)^{-\frac{1}{n}} x^{-\frac{1}{n}} t, \quad \alpha = \frac{1}{n} (n-1)^{\frac{1}{n}} x^{\frac{1}{n}};$$

and for the transformation of (III) we have

$$\epsilon^\theta = \frac{1}{n} (n-1)^{\frac{1}{n}} \epsilon^{\frac{\theta}{n}}, \quad D = nD',$$

$$u = (n-1)^{-\frac{m}{n}} \epsilon^{-\frac{m}{n}\theta} u'.$$

These substitutions being effected we arrive, after some slight reductions, at the following equation,

$$n^n [(n-1) D' - m]^{n-1} D' u' - (n-1) [nD' - m - 1]^n \epsilon^\theta u' = 0,$$

which, making  $m=1$  and  $u' = t$ , gives

$$n^n [(n-1) D' - 1]^{n-1} D' t - (n-1) [nD' - 2]^n \epsilon^\theta t = 0,$$

an equation which admits of reduction. In fact, operating on both members with  $(D' - 1)^{-1}$ , and determining the constant, as in the former case, by the aid of the Lagrangean expansion, we find

$$n^{n-1} [(n-1) D']^{n-1} t - (nD' - n - 1) [nD' - 2]^{n-2} \epsilon^\theta t = [n-1]^{n-1} \epsilon^\theta,$$

which is Mr Harley's second equation.

The references and deduction here given were to have been added to the memoir which is cited in page 189, according to Professor Boole's desire; but by some accident

they were not printed, and the omission was not discovered until after his death.

Mr Harley has lately succeeded in obtaining the following extension of Professor Boole's theorem.

The differential equation

$$\alpha^r \left[ x \frac{d}{dx} \right]^n u - \left[ \frac{n-r}{n} x \frac{d}{dx} + \frac{m}{n} - 1 \right]^{n-r} \left[ \frac{r}{n} x \frac{d}{dx} - \frac{m}{n} - 1 \right]^r x^r u = 0,$$

is satisfied by the  $m^{\text{th}}$  power of any root of the equation

$$y^n - xy^{n-r} + a = 0,$$

$u$  being considered as a function of  $x$ .

From this he deduces the following; the differential equation

$$n^n \left[ \frac{n-r}{r} x \frac{d}{dx} - \frac{m}{r} \right]^{n-r} \left[ x \frac{d}{dx} \right]^r u - (n-1)^r \left[ \frac{n}{r} x \frac{d}{dx} - \frac{m}{r} - 1 \right]^n x^r u = 0,$$

is satisfied by the  $m^{\text{th}}$  power of any root of the equation

$$y^n - ny^{n-r} + (n-1)x = 0.$$

For the materials of this Article I am indebted to Mr Harley.]

## CHAPTER XXXI.

### THE JACOBIAN THEORY OF THE LAST MULTIPLIER.

1. A SYSTEM of  $n$  differential equations of the first order and degree containing  $n + 1$  variables admits of  $n$  integrals of the form

$$u_1 = c_1, \quad u_2 = c_2, \quad \dots \quad u_n = c_n,$$

$u_1, u_2, \dots u_n$  being independent functions of the original variables. When  $n - 1$  of these integrals have been found they enable us to eliminate  $n - 1$  variables, with their differentials, from the given system of equations, and so to obtain a single final differential equation of the first order between the two remaining variables. The final equation admits of being made integrable by a factor, and its solution so found would constitute the  $n^{\text{th}}$  and last integral of the system. We propose in this Chapter to develop the theory of the above integrating factor as established by Jacobi. The term ‘principle of the last multiplier,’ which is more usually employed, seems objectionable; for the essence of Jacobi’s discovery consisted not in demonstrating the existence or the nature of the last integrating factor, but in the peculiar form of the method which he gave for its determination, and in the relations which are implied in that form. The discovery may be briefly said to consist in this; *viz.* that instead of forming by means of the  $n - 1$  known integrals the final differential equation between two variables and applying methods analogous to those of Chap. v., to determine its integrating factor, we construct antecedently to all integration a linear partial differential equation of the first order, any one integral of which

will enable us to assign an integrating factor of the final differential equation, *whatever the order of the previous integrations may have been*. Again, this partial differential equation depending for its construction only upon the form of the system given, we can often by examining it affirm beforehand that if all the integrals but one of the system be in any way found, the final integral will be deducible by quadratures. This happens in the case of the most important of all systems of differential equations—that of Dynamics.

Further, an ordinary differential equation of the  $n^{\text{th}}$  order being reducible to a system of  $n$  differential equations of the first order, Jacobi's theory may here also enable us to predicate the possibility of the last integration when the previous integrations have been effected.

Beginning with a single differential equation of the first order reduced to the form

$$\frac{dx}{X} = \frac{dy}{Y},$$

in which  $X$  and  $Y$  are functions of the two variables  $x$  and  $y$ , we know by Chap. v. that the integrating factor  $\mu$  will be given by the solution of the partial differential equation

$$\frac{d(\mu X)}{dx} + \frac{d(\mu Y)}{dy} = 0 \dots\dots\dots (1),$$

the form of which should be carefully noticed.

Consider next a system of two differential equations of the first order expressed in the general form

$$\frac{dx}{X} = \frac{dy}{Y} = \frac{dz}{Z} \dots\dots\dots (2),$$

$X$ ,  $Y$ , and  $Z$  being functions of the three variables  $x$ ,  $y$ ,  $z$ , and suppose one integral, represented by

$$\phi(x, y, z) = c \dots\dots\dots (3),$$

to be known. The function  $\phi(x, y, z)$ , or, as we shall express

it for brevity,  $\phi$ , will obviously satisfy the partial differential equation

$$X \frac{d\phi}{dx} + Y \frac{d\phi}{dy} + Z \frac{d\phi}{dz} = 0 \dots\dots\dots(4),$$

of which indeed the given equations form the Lagrangean auxiliary system; see Chap. XIV.

If from the given integral we determine  $z$  as a function of  $x$ ,  $y$  and  $c$ , and substitute its value in the first of the given differential equations, *viz.*

$$\frac{dx}{X} = \frac{dy}{Y},$$

the latter will be converted into a differential equation between  $x$  and  $y$ . But we may leave to the equation its prior form, provided that we regard  $X$  and  $Y$  as functions of the variables  $x$  and  $y$ , both explicitly as they appear therein, and implicitly as they are involved in  $z$ . And this being so, the equation (1) will become

$$\frac{d(\mu X)}{dx} + \frac{d(\mu X)}{dz} \frac{dz}{dx} + \frac{d(\mu Y)}{dy} + \frac{d(\mu Y)}{dz} \frac{dz}{dy} = 0.$$

The values of  $\frac{dz}{dx}$  and  $\frac{dz}{dy}$  in this equation must be found from the known integral (3); they are

$$\frac{dz}{dx} = -\frac{d\phi}{dx} \div \frac{d\phi}{dz}, \quad \frac{dz}{dy} = -\frac{d\phi}{dy} \div \frac{d\phi}{dz},$$

substituting which we have

$$\frac{d(\mu X)}{dx} \frac{d\phi}{dz} - \frac{d(\mu X)}{dz} \frac{d\phi}{dx} + \frac{d(\mu Y)}{dy} \frac{d\phi}{dz} - \frac{d(\mu Y)}{dz} \frac{d\phi}{dy} = 0 \dots (5).$$

This then is the partial differential equation for determining  $\mu$ . But the construction of this equation supposes  $\phi$  to be known. We propose to shew that  $\mu$  can be determined by a process in which the only partial differential equation to be solved can be constructed without the knowledge of  $\phi$ .

Since by actual differentiation

$$\frac{d}{dx} \left( A \frac{d\phi}{dz} \right) - \frac{d}{dz} \left( A \frac{d\phi}{dx} \right) = \frac{dA}{dx} \frac{d\phi}{dz} - \frac{dA}{dz} \frac{d\phi}{dx},$$

it follows, writing  $\mu X$  for  $A$ , that

$$\frac{d(\mu X)}{dx} \frac{d\phi}{dz} - \frac{d(\mu X)}{dz} \frac{d\phi}{dx} = \frac{d}{dx} \left( \mu X \frac{d\phi}{dz} \right) - \frac{d}{dz} \left( \mu X \frac{d\phi}{dx} \right).$$

Similarly

$$\frac{d(\mu Y)}{dy} \frac{d\phi}{dz} - \frac{d(\mu Y)}{dz} \frac{d\phi}{dy} = \frac{d}{dy} \left( \mu Y \frac{d\phi}{dz} \right) - \frac{d}{dz} \left( \mu Y \frac{d\phi}{dy} \right).$$

Lastly, we have

$$0 = \frac{d}{dz} \left( \mu Z \frac{d\phi}{dz} \right) - \frac{d}{dz} \left( \mu Z \frac{d\phi}{dz} \right).$$

Now adding the last three equations together we see that the first member of the result vanishes by (5): we have thus

$$\begin{aligned} & \frac{d}{dx} \left( \mu X \frac{d\phi}{dz} \right) + \frac{d}{dy} \left( \mu Y \frac{d\phi}{dz} \right) + \frac{d}{dz} \left( \mu Z \frac{d\phi}{dz} \right) \\ & - \frac{d}{dz} \left( \mu X \frac{d\phi}{dx} \right) - \frac{d}{dz} \left( \mu Y \frac{d\phi}{dy} \right) - \frac{d}{dz} \left( \mu Z \frac{d\phi}{dz} \right) = 0. \end{aligned}$$

The second line of the first member is equal to

$$- \frac{d}{dz} \left\{ \mu \left( X \frac{d\phi}{dx} + Y \frac{d\phi}{dy} + Z \frac{d\phi}{dz} \right) \right\},$$

and therefore vanishes by (4). There remains then

$$\frac{d}{dx} \left( \mu X \frac{d\phi}{dz} \right) + \frac{d}{dy} \left( \mu Y \frac{d\phi}{dz} \right) + \frac{d}{dz} \left( \mu Z \frac{d\phi}{dz} \right) = 0.$$

Hence if we put

$$\mu \frac{d\phi}{dz} = M,$$

we have

$$\frac{d(MX)}{dx} + \frac{d(MY)}{dy} + \frac{d(MZ)}{dz} = 0 \dots\dots\dots (6).$$

*If then by the solution of this equation a value of  $M$  distinct from 0 be found, the function  $\frac{M}{\frac{d\phi}{dz}}$  will be an integrating factor of that final differential equation which remains when  $z$  has been eliminated from the system (2) by means of any known integral  $\phi = c$ .*

It will be observed that the equation for  $M$  is analogous in form to the equation for  $\mu$  in the previous system. And this suggests the form of the general theorem.

Thus proceeding to the case of a system of three equations

$$\frac{dx}{X} = \frac{dy}{Y} = \frac{dz}{Z} = \frac{dt}{T},$$

we see that if

$$\psi(x, y, z, t) = c$$

be a known integral,  $\psi$  therefore satisfying the equation

$$X \frac{d\psi}{dx} + Y \frac{d\psi}{dy} + Z \frac{d\psi}{dz} + T \frac{d\psi}{dt} = 0 \dots\dots\dots (7),$$

then the system

$$\frac{dx}{X} = \frac{dy}{Y} = \frac{dz}{Z}$$

will virtually involve only the variables  $x, y, z$ , since  $t$

through the known integral becomes a function of  $x, y, z$ . The equation (6) now becomes

$$\begin{aligned} \frac{d(MX)}{dx} + \frac{d(MX)}{dt} \frac{dt}{dx} + \frac{d(MY)}{dy} + \frac{d(MY)}{dt} \frac{dt}{dy} \\ + \frac{d(MZ)}{dz} + \frac{d(MZ)}{dt} \frac{dt}{dz} = 0, \end{aligned}$$

or putting

$$\frac{dt}{dx} = -\frac{d\psi}{dx} \div \frac{d\psi}{dt}, \dots$$

$$\begin{aligned} \frac{d(MX)}{dx} \frac{d\psi}{dt} - \frac{d(MX)}{dt} \frac{d\psi}{dx} + \frac{d(MY)}{dy} \frac{d\psi}{dt} - \frac{d(MY)}{dt} \frac{d\psi}{dy} \\ + \frac{d(MZ)}{dz} \frac{d\psi}{dt} - \frac{d(MZ)}{dt} \frac{d\psi}{dz} = 0, \end{aligned}$$

and this is equivalent to

$$\begin{aligned} \frac{d\left(MX \frac{d\psi}{dt}\right)}{dx} + \frac{d\left(MY \frac{d\psi}{dt}\right)}{dy} + \frac{d\left(MZ \frac{d\psi}{dt}\right)}{dz} + \frac{d\left(MT \frac{d\psi}{dt}\right)}{dt} \\ - \frac{d}{dt} \left\{ M \left( X \frac{d\psi}{dx} + Y \frac{d\psi}{dy} + Z \frac{d\psi}{dz} + T \frac{d\psi}{dt} \right) \right\} = 0, \end{aligned}$$

and therefore becomes on rejecting the term in the second line by (7), and putting

$$M \frac{d\psi}{dt} = N,$$

$$\frac{d(NX)}{dx} + \frac{d(NY)}{dy} + \frac{d(NZ)}{dz} + \frac{d(NT)}{dt} = 0 \dots (8).$$

If from this equation a value of  $N$  distinct from 0 be obtained, then  $M = \frac{N}{\frac{d\psi}{dt}}$ , and therefore

$$\mu = \frac{N}{\frac{d\psi}{dt} \frac{d\phi}{dz}}.$$

This is the final multiplier, i. e. the integrating factor of the final differential equation between  $x$  and  $y$  which remains when  $z$  and  $t$  have been eliminated from the given system by means of the two known integrals. In calculating  $\mu$  from the above formula we must proceed as follows. The value of  $\frac{d\psi}{dt}$  must be found from any given integral  $\psi = c$ ; but that of  $\frac{d\phi}{dz}$  must be found from another integral from which by means of the former one  $t$  has been eliminated. Thus the general forms of the integrals will be

$$\psi(x, y, z, t) = c,$$

$$\phi(x, y, z, c) = c'.$$

Lastly, the values of  $\frac{d\psi}{dt}$ ,  $\frac{d\phi}{dz}$  found as above, and that of  $N$  given by any solution (distinct from 0) of the partial differential equation (8) having been substituted in the expression for  $\mu$ , we must eliminate  $z$  and  $t$  from that expression by means of the two known integrals. The resulting function of  $x, y, c$  and  $c'$  will be the integrating factor sought.

The reasoning above employed is in its nature quite independent of the number of the equations of the original system. The general theorem to which it leads may be thus stated.

**THEOREM.** The system of  $n$  differential equations

$$\frac{dx}{X} = \frac{dy_1}{Y_1} = \frac{dy_2}{Y_2} = \cdots \frac{dy_n}{Y_n}$$

being given, if a system of  $n - 1$  integrals

$$\phi_1 = c_1, \quad \phi_2 = c_2, \quad \dots \quad \phi_{n-1} = c_{n-1},$$

be so reduced by elimination that the variable  $y_1$  shall not appear in  $\phi_2$ , the variables  $y_1, y_2$  shall not appear in  $\phi_3$ , and so on, then the integrating factor  $\mu$  of that final differential equation between  $x$  and  $y_n$  will be given by the formula

$$\mu = \frac{M}{\frac{d\phi_1}{dy_1} \frac{d\phi_2}{dy_2} \dots \frac{d\phi_{n-1}}{dy_{n-1}}},$$

in which  $M$  represents any integral distinct from 0 of the partial differential equation

$$\frac{d(MX)}{dx} + \frac{d(MY_1)}{dy_1} \dots + \frac{d(MY_n)}{dy_n} = 0.$$

In applying this theorem the expression for  $\mu$  must be freed from all the variables except  $x$  and  $y_n$  by means of the given integrals.

This is Jacobi's theorem. On account of its great importance I propose to give another demonstration of it founded upon the Calculus of Variations.

## 2. *Second demonstration founded upon the Calculus of Variations.*

It will be most convenient to present the proposed system of differential equations under the symmetrical form

$$\frac{dx_1}{X_1} = \frac{dx_2}{X_2} = \dots = \frac{dx_n}{X_n},$$

the independent variables being  $x_1, x_2, \dots, x_n$  of which  $X_1, X_2, \dots, X_n$  are any functions. We have thus  $n - 1$  differential equations, and we are to seek the integrating factor of the differential equation which remains when by means of  $n - 2$  known integrals  $n - 2$  of the variables with their differentials have been eliminated.

Suppose  $P=c$  to be any integral of the system, then  $P$  satisfies, and it suffices that it satisfies, the partial differential equation

$$X_1 \frac{dP}{dx_1} + X_2 \frac{dP}{dx_2} \dots + X_n \frac{dP}{dx_n} = 0 \dots\dots\dots (\alpha).$$

Now if in place of  $x_1, x_2, \dots x_n$  we introduce a new system of independent variables  $u_1, u_2, \dots u_n$  which are functions of the former, then we shall have

$$\begin{aligned} X_1 \frac{dP}{dx_1} + X_2 \frac{dP}{dx_2} \dots + X_n \frac{dP}{dx_n} \\ = U_1 \frac{dP}{du_1} + U_2 \frac{dP}{du_2} \dots + U_n \frac{dP}{du_n}, \end{aligned}$$

$U_1, U_2, \dots U_n$  being functions of  $u_1, u_2, \dots u_n$ . And by the theory of the transformation of multiple integrals,

$$\begin{aligned} \int^n \left( X_1 \frac{dP}{dx_1} + X_2 \frac{dP}{dx_2} \dots + X_n \frac{dP}{dx_n} \right) dx_1 dx_2 \dots dx_n \\ = \int^n \frac{1}{H} \left( U_1 \frac{dP}{du_1} + U_2 \frac{dP}{du_2} \dots + U_n \frac{dP}{du_n} \right) du_1 du_2 \dots du_n, \end{aligned}$$

where

$$H = \begin{vmatrix} \frac{du_1}{dx_1} & \dots & \frac{du_1}{dx_n} \\ \dots & \dots & \dots \\ \frac{du_n}{dx_1} & \dots & \frac{du_n}{dx_n} \end{vmatrix}.$$

The foregoing equation we may express in the form

$$\Sigma \int^n X_i \frac{dP}{dx_i} dx_1 dx_2 \dots dx_n = \Sigma \int^n \frac{U_i}{H} \frac{dP}{du_i} du_1 du_2 \dots du_n.$$

Hence, representing by  $\delta$  an operation of differentiation which affects only the form of  $P$  as a function of  $x_1, x_2, \dots x_n$

or of  $u_1, u_2, \dots, u_n$ , and not the independent variables themselves, we have

$$\Sigma \int^n X_i \frac{d\delta P}{dx_i} dx_1 dx_2 \dots dx_n = \Sigma \int^n \frac{U_i}{H} \frac{d\delta P}{du_i} du_1 du_2 \dots du_n,$$

and therefore integrating by parts and equating the portions on each side which remain under the sign of  $n$ -fold integration,

$$\begin{aligned} & \Sigma \int^n \frac{dX_i}{dx_i} \delta P dx_1 dx_2 \dots dx_n \\ &= \Sigma \int^n \frac{d}{du_i} \left( \frac{U_i}{H} \right) \delta P du_1 du_2 \dots du_n. \end{aligned}$$

Whence again transforming the integral in the first member

$$\begin{aligned} & \Sigma \int^n \frac{dX_i}{dx_i} \delta P \frac{du_1 du_2 \dots du_n}{H} \\ &= \Sigma \int^n \frac{d}{du_i} \left( \frac{U_i}{H} \right) \delta P du_1 du_2 \dots du_n, \end{aligned}$$

and this being true quite irrespectively of the form of  $P$ , we have

$$\frac{1}{H} \Sigma \frac{dX_i}{dx_i} = \Sigma \frac{d}{du_i} \left( \frac{U_i}{H} \right).$$

In this equation Jacobi's theorem is virtually contained. For let the given equation be multiplied by any factor. Then changing in the above  $X_i$  into  $MX_i$ , and  $U_i$  into  $MU_i$ , we have

$$\frac{1}{H} \Sigma \frac{d(MX_i)}{dx_i} = \Sigma \frac{d}{du_i} \left( \frac{MU_i}{H} \right).$$

Hence, if  $M$  be determined to satisfy the equation

$$\Sigma \frac{d(MX_i)}{dx_i} = 0,$$

we shall have

$$\Sigma \frac{d}{du_i} \left( \frac{MU_i}{H} \right) = 0 \dots\dots\dots (b).$$

This is wholly independent of the relations connecting  $u_1, u_2, \dots u_n$  with  $x_1, x_2, \dots x_n$ . Now choose the  $n-2$  variables  $u_1, u_2, \dots u_{n-2}$  so that  $u_1 = c_1, u_2 = c_2, \dots u_{n-2} = c_{n-2}$  shall be integrals of the given partial differential equation (a). Then that equation transformed becomes

$$U_{n-1} \frac{dP}{du_{n-1}} + U_n \frac{dP}{du_n} = 0,$$

of which the auxiliary ordinary equation is

$$U_n du_{n-1} - U_{n-1} du_n = 0.$$

At the same time the equation (b) becomes

$$\frac{d}{du_{n-1}} \left( \frac{M}{H} U_{n-1} \right) + \frac{d}{du_n} \left( \frac{M}{H} U_n \right) = 0.$$

Hence  $\frac{M}{H}$  is the integrating factor of the preceding differential equation between  $u_{n-1}$  and  $u_n$ .

Jacobi's theorem in its most general form is thus seen to be the following

**THEOREM.** If the system of differential equations

$$\frac{dx_1}{X_1} = \frac{dx_2}{X_2} \dots = \frac{dx_n}{X_n}$$

be transformed by the introduction of a new system of variables  $u_1, u_2, \dots u_n$ , so chosen that

$$u_1 = c_1, u_2 = c_2, \dots u_{n-2} = c_{n-2}$$

shall be integrals of the given system, then the final differential equation between  $u_{n-1}$  and  $u_n$  shall have for its integrating

factor  $\frac{M}{H}$ , in which  $M$  is any function satisfying the partial differential equation

$$\frac{d(MX_1)}{dx_1} + \frac{d(MX_2)}{dx_2} + \dots + \frac{d(MX_n)}{dx_n} = 0,$$

and  $H$  stands for the determinant

$$\begin{vmatrix} \frac{du_1}{dx_1}, & \dots, & \frac{du_1}{dx_n} \\ \dots, & \dots, & \dots \\ \frac{du_n}{dx_1}, & \dots, & \frac{du_n}{dx_n} \end{vmatrix}.$$

The form of Jacobi's theorem obtained by the previous demonstration may be deduced from the above by choosing for  $u_{n-1}, u_n$  two of the original variables, for example  $x_{n-1}, x_n$ , and transforming the integrals  $u_1, u_2, \dots, u_{n-2}$  so that  $u_2$  shall contain only  $x_2 \dots x_n$ ,  $u_3$  shall contain only  $x_3 \dots x_n$ , and so on.

### *Examples.*

3. Jacobi has established by means of the above theorem the very remarkable theorem that in any ordinary dynamical problem the forces depending not upon the time but upon the material constitution of the system, if all the integrals but two of the dynamical equations are found, the two remaining integrals can be found by quadratures.

1st. In a dynamical system of free points the forces acting upon which depend only upon the position of the points, we have if we represent the entire system of rectangular co-ordinates taken in any order by  $x, y, z, \dots$  and the corresponding resolved forces divided each by the corresponding mass by  $X, Y, Z, \dots$  the system of equations

$$\frac{d^2x}{dt^2} = X, \quad \frac{d^2y}{dt^2} = Y, \dots$$

or putting

$$\frac{dx}{dt} = x', \quad \frac{dy}{dt} = y', \dots$$

$$dt = \frac{dx}{x'} = \frac{dy}{y'} \dots = \frac{dx'}{X} = \frac{dy'}{Y} \dots$$

Now as  $X, Y \dots$  do not contain  $t$  we may consider first the system

$$\frac{dx}{x'} = \frac{dy}{y'} \dots = \frac{dx'}{X} = \frac{dy'}{Y} \dots,$$

and it is evident that if we can find *all* the integrals of this system,  $t$  will be given by the equation

$$t = \int \frac{dx}{x'} + c,$$

$x'$  having been first converted by means of the supposed integrals into a function of  $x$ .

To determine the last multiplier of the system last written we have first the equation

$$\frac{d(Mx')}{dx} + \frac{d(My')}{dy} \dots + \frac{d(MX)}{dx'} + \frac{d(MY)}{dy'} \dots = 0,$$

which since  $X, Y \dots$  do not contain  $x', y' \dots$  is satisfied by  $M = \text{a constant}$ . Giving to the constant the particular value 1, we see that if

$$u_1 = c_1, \quad u_2 = c_2, \dots, \quad u_{n-2} = c_{n-2}$$

are  $n - 2$  integrals of the system, and if by means of these we eliminate  $n - 2$  of the variables and construct the differential equation between the two remaining variables, the integrating factor of that equation will be  $\frac{1}{H}$ , in which  $H$  is the functional determinant of  $u_1, u_2, \dots, u_n$ .

2ndly. Suppose the system subject to a material connexion which establishes an equation of condition among some or all of the co-ordinates. If we represent the co-ordinates taken in any order and multiplied each by the square root of the corresponding mass by  $x, y, \dots$  the corresponding resolved forces by  $X, Y, \dots$  and the equation of condition expressed by means of the above modified co-ordinates by  $\phi = 0$ , the differential equations will be

$$\frac{d^2x}{dt^2} = X + \lambda \frac{d\phi}{dx}, \quad \frac{d^2y}{dt^2} = Y + \lambda \frac{d\phi}{dy}, \dots,$$

the transformation above employed reducing all the equations to the same type. [See the next Chapter.]

Making

$$\frac{dx}{dt} = x', \quad \frac{dy}{dt} = y', \dots$$

the system becomes

$$dt = \frac{dx}{x'} = \frac{dy}{y'} \dots = \frac{dx'}{X + \lambda \frac{d\phi}{dx}} = \frac{dy'}{Y + \lambda \frac{d\phi}{dy}} \dots,$$

and the Jacobian equation for  $M$  becomes

$$\begin{aligned} \frac{d(Mx')}{dx} + \frac{d(My')}{dy} \dots + \frac{d\left\{M\left(X + \lambda \frac{d\phi}{dx}\right)\right\}}{dx'} \\ + \frac{d\left\{M\left(Y + \lambda \frac{d\phi}{dy}\right)\right\}}{dy'} \dots = 0. \end{aligned}$$

Now  $\phi$  does not contain  $x', y' \dots$ . Let us inquire whether it is possible to determine  $M$  also as a function of  $x, y \dots$  without  $x', y' \dots$  so as to satisfy the above differential equation.

The equation would become

$$x' \frac{dM}{dx} + y' \frac{dM}{dy} + \dots + M \left( \frac{d\lambda}{dx'} \frac{d\phi}{dx} + \frac{d\lambda}{dy'} \frac{d\phi}{dy} + \dots \right) = 0,$$

or if we write

$$x' \frac{d}{dx} + y' \frac{d}{dy} \dots = \delta,$$

$$\delta M + M \left( \frac{d\lambda}{dx'} \frac{d\phi}{dx} + \frac{d\lambda}{dy'} \frac{d\phi}{dy} + \dots \right) = 0,$$

and from this we must eliminate  $\lambda$ .

Now since  $\phi = 0$ , we have by differentiating and putting  $\frac{dx}{dt} = x', \dots$

$$x' \frac{d\phi}{dx} + y' \frac{d\phi}{dy} + \dots = 0,$$

and again differentiating

$$\begin{aligned} x'^2 \frac{d^2\phi}{dx^2} + y'^2 \frac{d^2\phi}{dy^2} + \dots + 2x'y' \frac{d^2\phi}{dx dy} + \dots \\ + \frac{d\phi}{dx} \frac{dx'}{dt} + \frac{d\phi}{dy} \frac{dy'}{dt} + \dots = 0, \end{aligned}$$

or since

$$\frac{dx'}{dt} = X + \lambda \frac{d\phi}{dx}, \dots$$

$$\begin{aligned} x'^2 \frac{d^2\phi}{dx^2} + y'^2 \frac{d^2\phi}{dy^2} + \dots + 2x'y' \frac{d^2\phi}{dx dy} + \dots \\ + X \frac{d\phi}{dx} + Y \frac{d\phi}{dy} + \dots \\ + \lambda \left\{ \left( \frac{d\phi}{dx} \right)^2 + \left( \frac{d\phi}{dy} \right)^2 + \dots \right\} = 0, \end{aligned}$$

and differentiating with respect to  $x'$ ,

$$2 \left( x' \frac{d^2 \phi}{dx^2} + y' \frac{d^2 \phi}{dx dy} + \dots \right) + \frac{d\lambda}{dx'} \left\{ \left( \frac{d\phi}{dx} \right)^2 + \left( \frac{d\phi}{dy} \right)^2 + \dots \right\} = 0,$$

or if we make

$$\left( \frac{d\phi}{dx} \right)^2 + \left( \frac{d\phi}{dy} \right)^2 + \dots = Q,$$

$$2\delta \frac{d\phi}{dx} + \frac{d\lambda}{dx'} Q = 0.$$

Similarly

$$2\delta \frac{d\phi}{dy} + \frac{d\lambda}{dy'} Q = 0,$$

.....

Therefore

$$\begin{aligned} 2 \frac{d\phi}{dx} \delta \frac{d\phi}{dx} + 2 \frac{d\phi}{dy} \delta \frac{d\phi}{dy} + \dots \\ + \left( \frac{d\lambda}{dx'} \frac{d\phi}{dx} + \frac{d\lambda}{dy'} \frac{d\phi}{dy} + \dots \right) Q = 0, \end{aligned}$$

or

$$\delta Q + \left( \frac{d\lambda}{dx'} \frac{d\phi}{dx} + \frac{d\lambda}{dy'} \frac{d\phi}{dy} + \dots \right) Q = 0,$$

and now eliminating  $\frac{d\lambda}{dx'} \frac{d\phi}{dx} + \frac{d\lambda}{dy'} \frac{d\phi}{dy} + \dots$

we obtain

$$Q\delta M - M\delta Q = 0,$$

which is satisfied by  $M = Q$ .

4. [Among Professor Boole's manuscripts I found five pages in German, forming part of a memoir, which was probably intended for Crelle's *Mathematical Journal*. The memoir was to have discussed two applications of the Calcu-

lus of Variations; one to the Jacobian Theory of the Last Multiplier, and the other to the Solution of Pfaff's equation

$$X_1 dx_1 + X_2 dx_2 + \dots + X_{2n} dx_{2n} = 0.$$

But there is only a single paragraph relating to the second application.

The manuscript contains the same demonstration of the Jacobian Theory of the Last Multiplier as in Art. 2 of the present Chapter; after this demonstration some remarks occur of which the substance will now be given.]

It is worthy of notice, that Jacobi in the 36th volume of Crelle's *Journal*, deduced by the aid of the Calculus of Variations the result on which the preceding demonstration of the Theory of the Last Multiplier depends. In fact, he shewed that if  $V$  denotes any function of

$$x_1, x_2, \dots x_n, z, \frac{dz}{dx_1}, \dots \frac{dz}{dx_n},$$

and  $V$  be transformed by the introduction of a new system of independent variables  $u_1, u_2, \dots u_n$ , then the following relation holds,

$$\begin{aligned} & \Delta \left( \frac{dV}{dz} - \frac{d}{dx_1} \frac{dV}{d \frac{dz}{dx_1}} - \dots - \frac{d}{dx_n} \frac{dV}{d \frac{dz}{dx_n}} \right) \\ &= \frac{d(\Delta V)}{dz} - \frac{d}{du_1} \frac{d(\Delta V)}{d \frac{dz}{du_1}} - \dots - \frac{d}{du_n} \frac{d(\Delta V)}{d \frac{dz}{du_n}}, \end{aligned}$$

where

$$\Delta = \begin{vmatrix} \frac{dx_1}{du_1}, & \dots & \frac{dx_1}{du_n} \\ \dots & \dots & \dots \\ \frac{dx_n}{du_1}, & \dots & \frac{dx_n}{du_n} \end{vmatrix}$$

Jacobi applies this result to the transformation of the expression

$$\frac{d^2 V}{dx^2} + \frac{d^2 V}{dy^2} + \frac{d^2 V}{dz^2}.$$

But neither Jacobi himself, nor any other person, so far as I know, has drawn attention to the application of the result which I have given here.

[The substance of the single paragraph relating to the second application of the Calculus of Variations will now be given.]

Clebsch has earned the thanks of all who are interested in the higher parts of the Theory of Differential Equations, since he has performed the same service for Pfaff's problem as Jacobi did for the Theory of Partial Differential Equations of the first order, and thereby for the equations of Dynamics. But while I recognise the great importance of the results, I consider it desirable to give a simpler deduction of the system of partial differential equations therein involved, and on which the other results depend.

## CHAPTER XXXII.

### THE DIFFERENTIAL EQUATIONS OF DYNAMICS.

[It will be seen that this is only a fragment of the Chapter which was to have appeared under this title.]

I do not propose in this Chapter to discuss the origin and interpretation of the differential equations of motion or to enter into those details of their application which are found in all ordinary treatises on Dynamics. But they constitute a system analytically so remarkable from the forms in which it is capable of being expressed, and from the general methods of integration which emerge out of those forms, that they are well deserving of a special attention.

Referred to rectangular co-ordinates the differential equations for the motion of a system of points free or connected are

$$\begin{aligned}
 m \frac{d^2x}{dt^2} &= X + \lambda \frac{d\phi}{dx} + \mu \frac{d\psi}{dx} \dots \\
 m \frac{d^2y}{dt^2} &= Y + \lambda \frac{d\phi}{dy} + \mu \frac{d\psi}{dy} \dots \\
 m \frac{d^2z}{dt^2} &= Z + \lambda \frac{d\phi}{dz} + \mu \frac{d\psi}{dz} \dots \\
 m' \frac{d^2x'}{dt^2} &= X' + \lambda \frac{d\phi}{dx'} + \mu \frac{d\psi}{dx'} \dots \\
 &\dots\dots\dots
 \end{aligned}$$

Here  $m$  is the mass at the point  $(x, y, z)$ ,  $m'$  that at  $(x', y', z')$ ,  $X, Y, Z$  the resolved forces at  $(x, y, z)$  tending severally to increase those co-ordinates, and so on. Lastly

$$\phi = 0, \quad \psi = 0, \dots$$

are the equations of condition each of which may involve all the co-ordinates, and  $\lambda, \mu \dots$  are indeterminate multipliers.

The above is usually termed the first Lagrangean form of the differential equations. In applying it we must either eliminate  $\lambda, \mu \dots$  from the given equations, and then by the equations of condition just so many of the co-ordinates with their differentials, or we must retain  $\lambda, \mu, \dots$  as variables so conditioned that the values of  $\frac{d^2x}{dt^2}, \frac{d^2y}{dt^2}, \dots$  in the system shall satisfy identically the differential equations involving  $\frac{d^2x}{dt^2}, \frac{d^2y}{dt^2}, \dots$  derived from  $\phi = 0, \psi = 0, \dots$  viz. the equations

$$\frac{d^2\phi}{dt^2} = 0, \quad \frac{d^2\psi}{dt^2} = 0, \dots$$

The first Lagrangean system may by a slight transformation be reduced to a form in which all the equations are of one type, viz. of the type which they would have if all the masses were equal to unity.

For taking the first equation of the system and dividing by  $m^{\frac{1}{2}}$  we may express the result in the form

$$\frac{d^2(m^{\frac{1}{2}}x)}{dt^2} = \frac{X}{m^{\frac{1}{2}}} + \lambda \frac{d\phi}{d(m^{\frac{1}{2}}x)} + \mu \frac{d\psi}{d(m^{\frac{1}{2}}x)} \dots$$

from which we see that if  $x, y \dots$  had been taken to represent the entire system of co-ordinates taken in any order and multiplied each by the square root of the corresponding mass, and  $X, Y \dots$  the corresponding resolved forces taken in the same order and *divided* each by the square root of the corresponding mass, the system of equations would have been

$$\frac{d^2x}{dt^2} = X + \lambda \frac{d\phi}{dx} + \mu \frac{d\psi}{dx} \dots$$

$$\frac{d^2y}{dt^2} = Y + \lambda \frac{d\phi}{dy} + \mu \frac{d\psi}{dy} \dots$$

.....

all being of one type. In general investigations this form is to be preferred.

From the first Lagrangean form another known as the second Lagrangean, and from this again a third known as the Hamiltonian are derived. The second Lagrangean form is properly speaking an expression for the effect of a transformation of co-ordinates in the most general sense upon the original system, i.e. of a transformation which in place of  $x, y, \dots$  the entire system of given co-ordinates substitutes a new system of variables  $\xi, \eta, \dots$  the expressions of which as functions of  $x, y, \dots$  are known. It is not necessary that this new system of variables should be co-ordinates in the proper sense of that term, determining three by three the positions of the several masses; it suffices that they should in their entirety determine and be determined by the co-ordinates given.

The second Lagrangean form may be established as follows:

Differentiating the equations  $\phi = 0, \psi = 0, \dots$  with respect to any one of the new variables  $\xi$  we have

$$\frac{d\phi}{dx} \frac{dx}{d\xi} + \frac{d\phi}{dy} \frac{dy}{d\xi} \dots = 0,$$

$$\frac{d\psi}{dx} \frac{dx}{d\xi} + \frac{d\psi}{dy} \frac{dy}{d\xi} \dots = 0;$$

whence if we multiply the equations of the given system by  $\frac{dx}{d\xi}, \frac{dy}{d\xi}, \dots$  and add, we have

$$\frac{dx}{d\xi} \frac{d^2x}{dt^2} + \frac{dy}{d\xi} \frac{d^2y}{dt^2} \dots = X \frac{dx}{d\xi} + Y \frac{dy}{d\xi} \dots$$

## CHAPTER XXXIII.

### ON THE PROJECTION OF A SURFACE ON A PLANE.

[THE following memoir was found among Professor Boole's manuscripts; a Title and Introductory Remarks were to have been prefixed, but with this exception the memoir appears to be finished for publication. It is sufficiently connected with the subject of Differential Equations to find a place in the present volume.

The memoir by Sir John Herschel to which allusion is made is entitled, *On a new Projection of the Sphere*; this was read before the Royal Geographical Society of London on the 11th of April, 1859, and was printed as part of the Journal of the Society, Vol. xxx. 1860, pages 100...106. A chart of the World on Sir John Herschel's projection has been published by A. and C. Black of Edinburgh.

The history of the subject will be found in Chapter XXIII. of the *Coup d'œil historique sur la Projection des Cartes de Géographie...* Par M. D'Avezac, Paris, 1863.

For the materials of this introductory notice I am indebted to Sir John Herschel.]

1. Let  $x, y, z$  be the rectangular co-ordinates of any point on the given surface;  $x', y'$  the co-ordinates of the corresponding point on the plane of projection. Let the equation of the given surface be

$$F(x, y, z) = 0;$$

or, for simplicity,

$$F = 0.$$

The condition of projection upon which Sir John Herschel's investigations are founded, and which we shall adopt here, is that of the similarity of corresponding infinitesimal areas on the surface and on the plane. The object of the problem then in general is the discovery of the mode in which  $x'$ ,  $y'$  depend upon  $x$ ,  $y$ , and  $z$  in accordance with the above condition; its object in any particular case is the determination of  $x'$ ,  $y'$  as functions of  $x$ ,  $y$ ,  $z$ .

Regarding then  $x'$ ,  $y'$  as ultimately functions of  $x$ ,  $y$ ,  $z$  we have

$$dx' = \frac{dx'}{dx} dx + \frac{dx'}{dy} dy + \frac{dx'}{dz} dz,$$

$$dy' = \frac{dy'}{dx} dx + \frac{dy'}{dy} dy + \frac{dy'}{dz} dz,$$

in which  $dx$ ,  $dy$ ,  $dz$  are not independent, but are connected by the condition

$$\frac{dF}{dx} dx + \frac{dF}{dy} dy + \frac{dF}{dz} dz = 0.$$

Now for brevity write

$$\frac{dx'}{dx} = a, \quad \frac{dx'}{dy} = b, \quad \frac{dx'}{dz} = c,$$

$$\frac{dy'}{dx} = a', \quad \frac{dy'}{dy} = b', \quad \frac{dy'}{dz} = c',$$

$$\frac{dF}{dx} = A, \quad \frac{dF}{dy} = B, \quad \frac{dF}{dz} = C;$$

then

$$dx' = a dx + b dy + c dz \dots\dots\dots (1),$$

$$dy' = a' dx + b' dy + c' dz \dots\dots\dots (2),$$

$$0 = A dx + B dy + C dz \dots\dots\dots (3).$$

Now the condition of the similarity of infinitesimal corresponding areas may be resolved into the two following conditions, viz.:

1st. The equality of their corresponding angles.

2ndly. The proportionality of their corresponding sides.

And these conditions we shall introduce separately.

1st. Assuming any point  $x', y'$  on the plane of projection, let  $x'$  alone vary, and the infinitesimal line generated is  $dx'$ , while (since  $dy' = 0$ ) (2) and (3) become

$$a'dx + b'dy + c'dz = 0,$$

$$A'dx + B'dy + C'dz = 0,$$

whence, if we write

$$L = Bc' - Cb', \quad M = Ca' - Ac', \quad N = Ab' - Ba',$$

we have 
$$\frac{dx}{L} = \frac{dy}{M} = \frac{dz}{N} \dots\dots\dots (4),$$

so that the direction cosines of the infinitesimal line on the surface  $L'$  corresponding to the line  $dx'$  on the plane ( $x', y'$ ) will be

$$\frac{L}{(L^2 + M^2 + N^2)^{\frac{1}{2}}}, \quad \frac{M}{(L^2 + M^2 + N^2)^{\frac{1}{2}}}, \quad \frac{N}{(L^2 + M^2 + N^2)^{\frac{1}{2}}} \dots\dots\dots (5).$$

In like manner, if  $y'$  alone vary, we shall find for the direction cosines of the infinitesimal line on the surface  $L'$  which corresponds to  $dy'$  on the plane

$$\frac{L'}{(L'^2 + M'^2 + N'^2)^{\frac{1}{2}}}, \quad \frac{M'}{(L'^2 + M'^2 + N'^2)^{\frac{1}{2}}}, \quad \frac{N'}{(L'^2 + M'^2 + N'^2)^{\frac{1}{2}}} \dots\dots\dots (6),$$

where  $L' = Bc - Cb$ ,  $M' = Ca - Ac$ ,  $N' = Ab - Ba$ .

By the first of the conditions of similarity the angle between these lines on the surface must be a right angle since

$dx'$  and  $dy'$  are at right angles. Hence we have, from (5) and (6),

$$LL' + MM' + NN' = 0 \dots\dots\dots(7).$$

2ndly. The ratio of the length of the element  $dx'$  to the corresponding element on the surface is

$$\frac{dx'}{\sqrt{dx^2 + dy^2 + dz^2}},$$

or, by (1),

$$\frac{adx + bdy + cdz}{\sqrt{dx^2 + dy^2 + dz^2}},$$

and therefore by (4)

$$\frac{aL + bM + cN}{\sqrt{L^2 + M^2 + N^2}},$$

equating which to the corresponding expression for the ratio of the length of  $dy'$  to that of its projection on the surface, we have

$$\frac{aL + bM + cN}{\sqrt{L^2 + M^2 + N^2}} = \frac{a'L' + b'M' + c'N'}{\sqrt{L'^2 + M'^2 + N'^2}} \dots\dots\dots(8).$$

Now if we substitute for  $L, M, N, L', M', N'$  their values, we shall find

$$aL + bM + cN = A(b'c - bc') + B(c'a - ca') + C(a'b - ab'),$$

$$a'L' + b'M' + c'N' = A(bc' - b'c) + B(ca' - c'a) + C(ab' - a'b),$$

and the second members of these equations differ only in sign.

Thus (8) may be expressed in the form

$$\left\{ A(b'c - bc') + B(c'a - ca') + C(a'b - ab') \right\} \\ \times \left\{ \frac{1}{(L^2 + M^2 + N^2)^{\frac{1}{2}}} - \frac{1}{(L'^2 + M'^2 + N'^2)^{\frac{1}{2}}} \right\} = 0 \dots(9).$$

But the first factor of the first member of this equation being the determinant of the system

$$adx + bdy + cdz = 0,$$

$$a'dx + b'dy + c'dz = 0,$$

$$Adx + Bdy + Cdz = 0,$$

expresses when equated to zero the condition that if in the system (1), (2), (3)  $dy'$  vanishes  $dx'$  shall also vanish; and  $dx'$  and  $dy'$  being independent, this condition cannot be satisfied, so that (9) reduces to

$$\frac{1}{(L^2 + M^2 + N^2)^{\frac{1}{2}}} - \frac{1}{(L'^2 + M'^2 + N'^2)^{\frac{1}{2}}} = 0,$$

whence

$$L'^2 + M'^2 + N'^2 - L^2 - M^2 - N^2 = 0 \dots\dots\dots(10),$$

and this, with (7), will fully express the conditions of similarity.

2. If we multiply (7) by  $2\sqrt{-1}$ , and add and subtract the result from (10), we obtain the equivalent system

$$\left. \begin{aligned} (L' + L\sqrt{-1})^2 + (M' + M\sqrt{-1})^2 + (N' + N\sqrt{-1})^2 &= 0 \\ (L' - L\sqrt{-1})^2 + (M' - M\sqrt{-1})^2 + (N' - N\sqrt{-1})^2 &= 0 \end{aligned} \right\} \dots(11).$$

$$\begin{aligned} \text{Now } L' \pm L\sqrt{-1} &= \frac{dF}{dy} \frac{dx'}{dz} - \frac{dF}{dz} \frac{dx'}{dy} \\ &\quad \pm \left( \frac{dF}{dy} \frac{dy'}{dz} - \frac{dF}{dz} \frac{dy'}{dy} \right) \sqrt{-1} \\ &= \frac{dF}{dy} \frac{d(x' \pm y'\sqrt{-1})}{dz} - \frac{dF}{dz} \frac{d(x' \pm y'\sqrt{-1})}{dy}. \end{aligned}$$

Writing then

$$x' + y' \sqrt{-1} = u, \quad x' - y' \sqrt{-1} = v,$$

we have

$$L' + L\sqrt{-1} = \frac{dF}{dy} \frac{du}{dz} - \frac{dF}{dz} \frac{du}{dy},$$

$$L' - L\sqrt{-1} = \frac{dF}{dy} \frac{dv}{dz} - \frac{dF}{dz} \frac{dv}{dy}.$$

In the same way

$$M' + M\sqrt{-1} = \frac{dF}{dz} \frac{du}{dx} - \frac{dF}{dx} \frac{du}{dz},$$

$$M' - M\sqrt{-1} = \frac{dF}{dz} \frac{dv}{dx} - \frac{dF}{dx} \frac{dv}{dz},$$

$$N' + N\sqrt{-1} = \frac{dF}{dx} \frac{du}{dy} - \frac{dF}{dy} \frac{du}{dx},$$

$$N' - N\sqrt{-1} = \frac{dF}{dx} \frac{dv}{dy} - \frac{dF}{dy} \frac{dv}{dx}.$$

Substituting which in the system (11) there result

$$\left. \begin{aligned} & \left( \frac{dF}{dy} \frac{du}{dz} - \frac{dF}{dz} \frac{du}{dy} \right)^2 + \left( \frac{dF}{dz} \frac{du}{dx} - \frac{dF}{dx} \frac{du}{dz} \right)^2 \\ & \quad + \left( \frac{dF}{dx} \frac{du}{dy} - \frac{dF}{dy} \frac{du}{dx} \right)^2 = 0 \\ & \left( \frac{dF}{dy} \frac{dv}{dz} - \frac{dF}{dz} \frac{dv}{dy} \right)^2 + \left( \frac{dF}{dz} \frac{dv}{dx} - \frac{dF}{dx} \frac{dv}{dz} \right)^2 \\ & \quad + \left( \frac{dF}{dx} \frac{dv}{dy} - \frac{dF}{dy} \frac{dv}{dx} \right)^2 = 0 \end{aligned} \right\} \dots (12),$$

to which we may give the somewhat more convenient form

$$\left\{ \left( \frac{dF}{dx} \right)^2 + \left( \frac{dF}{dy} \right)^2 + \left( \frac{dF}{dz} \right)^2 \right\} \left\{ \left( \frac{du}{dx} \right)^2 + \left( \frac{du}{dy} \right)^2 + \left( \frac{du}{dz} \right)^2 \right\} \\ - \left( \frac{dF}{dx} \frac{du}{dx} + \frac{dF}{dy} \frac{du}{dy} + \frac{dF}{dz} \frac{du}{dz} \right)^2 = 0 \dots (I).$$

$$\left\{ \left( \frac{dF}{dx} \right)^2 + \left( \frac{dF}{dy} \right)^2 + \left( \frac{dF}{dz} \right)^2 \right\} \left\{ \left( \frac{dv}{dx} \right)^2 + \left( \frac{dv}{dy} \right)^2 + \left( \frac{dv}{dz} \right)^2 \right\} \\ - \left( \frac{dF}{dx} \frac{dv}{dx} + \frac{dF}{dy} \frac{dv}{dy} + \frac{dF}{dz} \frac{dv}{dz} \right)^2 = 0 \dots (II).$$

These are partial differential equations of the first order, serving to determine  $u$  and  $v$  as functions of  $x, y, z$ .

But it is not necessary to solve the equations in their general form. For,  $x, y$ , and  $z$  being connected by the equation of the surface, the above equations may always be so reduced as to involve only two independent variables. As latitude and longitude determine the position of a point on the earth, so two co-ordinates of any given species will determine the position of a point on the given surface, and these co-ordinates, when fixed upon, become the independent variables of the problem.

Let  $s$  and  $t$  represent such co-ordinates, and let their expressions in terms of  $x, y, z$  give

$$s = \phi_1(x, y, z), \quad t = \phi_2(x, y, z),$$

which equations combined with that of the given surface will reciprocally determine  $x, y, z$  as functions of  $s$  and  $t$ . Then 1st the differential coefficients of  $F'$  which in the equations (I), (II), are functions of  $x, y, z$  may be transformed into functions of  $s$  and  $t$ ; 2ndly, we have

$$\frac{du}{dx} = \frac{du}{ds} \frac{ds}{dx} + \frac{du}{dt} \frac{dt}{dx}, \\ \frac{du}{dy} = \frac{du}{ds} \frac{ds}{dy} + \frac{du}{dt} \frac{dt}{dy}, \\ \frac{du}{dz} = \frac{du}{ds} \frac{ds}{dz} + \frac{du}{dt} \frac{dt}{dz},$$

and as  $\frac{ds}{dx}$ ,  $\frac{dt}{dx}$ ... are known functions of  $x$ ,  $y$ ,  $z$ , they also are expressible in terms of  $s$  and  $t$ . The result of these substitutions will then be to convert (I) into a partial differential equation in which  $u$  is the dependent and  $s$  and  $t$  the independent variables, and this equation being, like (I), of the first order and second degree in the differential coefficients of  $u$ , will be of the form

$$P \left( \frac{du}{ds} \right)^2 + Q \frac{du}{ds} \frac{du}{dt} + R \left( \frac{du}{dt} \right)^2 = 0.$$

For  $v$  we shall have an exactly similar equation with the same coefficients.

The above equation is, by the solution of a quadratic, resolvable into two equations of the form

$$\frac{du}{ds} - \lambda_1 \frac{du}{dt} = 0, \quad \frac{du}{ds} - \lambda_2 \frac{du}{dt} = 0.$$

To these correspond the respective auxiliary equations

$$dt + \lambda_1 ds = 0, \quad dt + \lambda_2 ds = 0 \dots\dots\dots (13).$$

If the integrals of these are

$$S = c_1, \quad T = c_2,$$

respectively, then we have

$$u = \phi(S), \quad u = \psi(T).$$

Now  $v$  being determinable by an equation of the same form as  $u$ , it follows that of the above two values of  $u$  one must be assigned to  $v$ , so that the solution of the problem will be contained in the system

$$u = \phi(S), \quad v = \psi(T),$$

or in the system

$$u = \phi(T), \quad v = \psi(S).$$

The particular forms of the arbitrary functions  $\phi$  and  $\psi$  will depend solely upon the nature of the problem under consideration.

One other point remains to be noticed. The first members of (12) are essentially positive, being composed of squares; so are then the first members of (I), (II); and so, if the intermediate transformations are real, is the first member of the equation whose coefficients are  $P$ ,  $Q$ ,  $R$ . Hence the quadratic determining  $\lambda_1, \lambda_2$  will have imaginary roots of the form  $\alpha \pm \beta \sqrt{-1}$ . Ultimately therefore it will suffice to integrate one equation of the system (13) and then to deduce the solution of the other by changing  $\sqrt{-1}$  into  $-\sqrt{-1}$ .

3. *Application of the above formulæ when the given surface is an oblate spheroid, such as the earth.*

Let the plane of the equator be that of projection, the centre being the origin. Let the co-ordinates  $x, y$  pass through the meridians of  $0$  and of  $90^\circ$  respectively, and  $z$  through the poles. The equation of the surface will be

$$\frac{x^2 + y^2}{a^2} + \frac{z^2}{b^2} = 1 \dots\dots\dots (14),$$

where  $a$  is the earth's equatorial,  $b$  its polar radius. Let also the latitude of the point  $x, y, z$  be represented by  $s$ , the longitude by  $t$ . We have

$$F = \frac{x^2 + y^2}{a^2} + \frac{z^2}{b^2} - 1,$$

$$\frac{dF}{dx} = \frac{2x}{a^2}, \quad \frac{dF}{dy} = \frac{2y}{a^2}, \quad \frac{dF}{dz} = \frac{2z}{b^2},$$

and substituting in (I),

$$\left( \frac{x^2}{a^4} + \frac{y^2}{b^4} + \frac{z^2}{b^4} \right) \left\{ \left( \frac{du}{dx} \right)^2 + \left( \frac{du}{dy} \right)^2 + \left( \frac{du}{dz} \right)^2 \right\} \\ - \left( \frac{x}{a^2} \frac{du}{dx} + \frac{y}{a^2} \frac{du}{dy} + \frac{z}{b^2} \frac{du}{dz} \right)^2 = 0,$$

or, if we represent  $\frac{a^2}{b^2}$  by  $h^2$ ,

$$(x^2 + y^2 + h^2 z^2) \left\{ \left( \frac{du}{dx} \right)^2 + \left( \frac{du}{dy} \right)^2 + \left( \frac{du}{dz} \right)^2 \right\} - \left( x \frac{du}{dx} + y \frac{du}{dy} + h^2 z \frac{du}{dz} \right)^2 = 0 \dots\dots\dots (15).$$

Now as  $x, y$  are rectangular co-ordinates in the plane of the equator, and  $x$  passes through the first meridian, we have

$$\frac{y}{x} = \tan t.$$

Again, representing in the annexed figure the meridian of the point  $P$ , or  $(x, y, z)$  touched by the straight line  $QR$  in the same plane, we have  $CM = \sqrt{x^2 + y^2}$ ,  $MP = z$ . Therefore if  $\sqrt{x^2 + y^2} = r$ , the equation of the meridian is

$$\frac{r^2}{a^2} + \frac{z^2}{b^2} = 1,$$

that of the tangent

$$\frac{rr'}{a^2} + \frac{zz'}{b^2} = 1,$$

$r', z'$  being current rectangular co-ordinates of the tangent. Hence

$$\tan CQR = \frac{a^2 z}{b^2 r} = \frac{h^2 z}{\sqrt{x^2 + y^2}}.$$

But  $CQR = \text{latitude}$ . Therefore finally

$$s = \tan^{-1} \frac{h^2 z}{\sqrt{x^2 + y^2}}, \quad t = \tan^{-1} \frac{y}{x} \dots\dots\dots (16),$$

and we must now transform (15) so as to make  $s$  and  $t$  the independent variables.

From the above equations combined with (14) we find

$$x = \frac{ah \cos t}{\sqrt{h^2 + \tan^2 s}}, \quad y = \frac{ah \sin t}{\sqrt{h^2 + \tan^2 s}}, \quad z = \frac{a \tan s}{h \sqrt{h^2 + \tan^2 s}}, \dots (17),$$

and substituting in (15),

$$\sec^2 s \left\{ \left( \frac{du}{dx} \right)^2 + \left( \frac{du}{dy} \right)^2 + \left( \frac{du}{dz} \right)^2 \right\} - \left( \cos t \frac{du}{dx} + \sin t \frac{du}{dy} + \tan s \frac{du}{dz} \right)^2 = 0 \dots\dots (18).$$

Again,

$$\frac{du}{dx} = \frac{du}{ds} \frac{ds}{dx} + \frac{du}{dt} \frac{dt}{dx},$$

$$\frac{du}{dy} = \frac{du}{ds} \frac{ds}{dy} + \frac{du}{dt} \frac{dt}{dy},$$

$$\frac{du}{dz} = \frac{du}{ds} \frac{ds}{dz} + \frac{du}{dt} \frac{dt}{dz}.$$

$$\text{Now } \frac{ds}{dx} = \frac{-h^2 zx}{\sqrt{x^2 + y^2} (x^2 + y^2 + h^4 z^2)} = \frac{-\sin s \cos s \cos t \sqrt{H}}{ah},$$

where  $H = h^2 + \tan^2 s$ . In like manner

$$\frac{ds}{dy} = \frac{-\sin s \cos s \sin t \sqrt{H}}{ah},$$

$$\frac{ds}{dz} = \frac{h \cos^2 s \sqrt{H}}{a},$$

$$\frac{dt}{dx} = \frac{-\sin t \sqrt{H}}{ah},$$

$$\frac{dt}{dy} = \frac{\cos t \sqrt{H}}{ah},$$

$$\frac{dt}{dz} = 0.$$

Hence

$$\frac{du}{dx} = \frac{\sqrt{H}}{ah} \left( -\sin s \cos s \cos t \frac{du}{ds} - \sin t \frac{du}{dt} \right),$$

$$\frac{du}{dy} = \frac{\sqrt{H}}{ah} \left( -\sin s \cos s \sin t \frac{du}{ds} + \cos t \frac{du}{dt} \right),$$

$$\frac{du}{dz} = \frac{\sqrt{H}}{ah} \left( h^2 \cos^2 s \frac{du}{ds} \right).$$

Substituting these values in (18), and dividing by the common factor  $\frac{H}{a^2 h^2}$ , we have on reduction

$$\left( \frac{du}{dt} \right)^2 + \cos^2 s \{1 + (h^2 - 1) \cos^2 s\}^2 \left( \frac{du}{ds} \right)^2 = 0,$$

which is resolvable into

$$\frac{du}{dt} - \sqrt{-1} \cos s \{1 + (h^2 - 1) \cos^2 s\} \frac{du}{ds} = 0,$$

$$\frac{du}{dt} + \sqrt{-1} \cos s \{1 + (h^2 - 1) \cos^2 s\} \frac{du}{ds} = 0,$$

partial differential equations of which the integrals are included in the common formula

$$u = \phi \left( \int \frac{ds}{\cos s \{1 + (h^2 - 1) \cos^2 s\}} \pm t \sqrt{-1} \right).$$

$$\begin{aligned} \text{Now } & \int \frac{ds}{\cos s \{1 + (h^2 - 1) \cos^2 s\}} \\ &= \int \frac{ds}{\cos s} + (1 - h^2) \int \frac{\cos s \, ds}{1 + (h^2 - 1) \cos^2 s} \\ &= \int \frac{ds}{\cos s} + (1 - h^2) \int \frac{\cos s \, ds}{h^2 - (h^2 - 1) \sin^2 s} \end{aligned}$$

$$\begin{aligned}
&= \int \frac{ds}{\cos s} - e^2 \int \frac{\cos s \, ds}{1 - e^2 \sin^2 s}, \quad \left( \text{since } e^2 = \frac{a^2 - b^2}{a^2} \right) \\
&= \log \tan \left( \frac{\pi}{4} + \frac{s}{2} \right) + \frac{e}{2} \log \frac{1 - e \sin s}{1 + e \sin s} \\
&= \log \left\{ \left( \frac{1 - e \sin s}{1 + e \sin s} \right)^{\frac{e}{2}} \tan \left( \frac{\pi}{4} + \frac{s}{2} \right) \right\}.
\end{aligned}$$

Hence

$$u = \phi \left[ \log \left\{ \left( \frac{1 - e \sin s}{1 + e \sin s} \right)^{\frac{e}{2}} \tan \left( \frac{\pi}{4} + \frac{s}{2} \right) \right\} \pm t \sqrt{-1} \right],$$

or, changing  $\phi(t)$  into  $\phi(\epsilon')$ ,

$$u = \phi \left\{ \left( \frac{1 - e \sin s}{1 + e \sin s} \right)^{\frac{e}{2}} \tan \left( \frac{\pi}{4} + \frac{s}{2} \right) \epsilon^{\pm t \sqrt{-1}} \right\},$$

$$v = \psi \left\{ \left( \frac{1 - e \sin s}{1 + e \sin s} \right)^{\frac{e}{2}} \tan \left( \frac{\pi}{4} + \frac{s}{2} \right) \epsilon^{\mp t \sqrt{-1}} \right\}.$$

Let  $r$  and  $\theta$  be the polar co-ordinates of that point in the plane of projection which corresponds to the point whose latitude and longitude on the surface are  $s$  and  $t$ ; and let

$$S = \left( \frac{1 - e \sin s}{1 + e \sin s} \right)^{\frac{e}{2}} \tan \left( \frac{\pi}{4} + \frac{s}{2} \right),$$

then the complete solution assumes the very simple form

$$r \epsilon^{\theta \sqrt{-1}} = \phi(S \epsilon^{\pm t \sqrt{-1}}), \quad r \epsilon^{-\theta \sqrt{-1}} = \psi(S \epsilon^{\mp t \sqrt{-1}}) \dots \dots (\text{III}).$$

Of particular deductions the most interesting is that which arises from the supposition that the parallels of latitude are projected into circles round the pole. This requires that  $r$

should be independent of  $t$ , a condition which is satisfied in the most general manner by assuming

$$\phi(t) = Ct^n, \quad \psi(t) = C't^n,$$

we then find

$$r\epsilon^{\theta\sqrt{-1}} = CS^n\epsilon^{\pm nt\sqrt{-1}}, \quad r\epsilon^{-\theta\sqrt{-1}} = C'S^n\epsilon^{\mp nt\sqrt{-1}},$$

whence, on multiplication and division,

$$r^2 = CC'S^{2n}, \quad \epsilon^{2\theta\sqrt{-1}} = \frac{C}{C'}\epsilon^{\pm 2nt\sqrt{-1}},$$

whence,  $A$  and  $B$  being new arbitrary constants derived from  $C$  and  $C'$

$$r = AS^n, \quad \theta = \pm nt + B.$$

If we observe that  $\theta$  and  $t$  should vanish together, we have  $B=0$ , and the equation  $\theta = \pm nt$  shews that the surface of the sphere will be projected into a sector of a circle, the arc of which is to the circumference of the circle as  $n : 1$ . Thus, if  $n = \frac{1}{4}$ , the sphere is projected upon a quadrant, and so on.

The other equation gives

$$r = A \left\{ \tan \left( \frac{\pi}{4} + \frac{s}{2} \right) \right\}^n \left( \frac{1 - e \sin s}{1 + e \sin s} \right)^{\frac{ne}{2}}.$$

If  $s=0$  we find  $r=A$ , whence  $A$  is the distance of the equator from the pole in the plane of projection, and if that distance, which is arbitrary, be assumed as the unit, we have

$$r = \tan \left\{ \left( \frac{\pi}{4} + \frac{s}{2} \right) \right\}^n \left( \frac{1 - e \sin s}{1 + e \sin s} \right)^{\frac{ne}{2}}$$

for the distance from the pole of that parallel whose latitude is  $s$ . We may give to this expression a better form by

assuming  $p = \frac{\pi}{2} + s$ , and introducing an auxiliary quantity  $q$  determined by the equation

$$e \cos p = \cos q.$$

We have then

$$r = \left( \tan \frac{p}{2} \right)^n \left( \cot \frac{q}{2} \right)^{n_0}.$$

The following table gives the values of  $r$  for the sphere and for the spheroid whose eccentricity is  $\cdot 08$  (which is about that of the earth), for each ten degrees of polar distance, for the values  $n = 1$ , and  $n = \frac{1}{4}$ .

# THE INTEGRAL CALCULUS

By J. W. EDWARDS

A leisurely, immensely detailed, textbook of over 1,900 pages, rich in illustrative examples and manipulative techniques and containing much interesting material that must of necessity be omitted from less comprehensive works.

There are forty large chapters in all. The earlier cover a leisurely and a more-than-usually-detailed treatment of all the elementary standard topics. Later chapters include: Jacobian Elliptic Functions, Weierstrassian Elliptic Functions, Evaluation of Definite Integrals, Harmonic Analysis, Calculus of Variations, etc. Every chapter contains many exercises (with solutions).

2 vols. 1,922 pp.  $5 \times 8$ . Originally published at \$31.50 the set.  
Each volume **\$7.50**

# AUTOMORPHIC FUNCTIONS

By L. R. FORD

—2nd ed. (Cor. repr. of 1st ed.) x + 333 pp.  $5\frac{3}{8} \times 8$ . **\$4.95**

## SET THEORY

By F. HAUSDORFF

Now for the first time available in English, Hausdorff's classic text-book has been an inspiration and a delight to those who have read it in the original German. The translation is from the Third (latest) German edition.

"We wish to state without qualification that this is an indispensable book for all those interested in the theory of sets and the allied branches of real variable theory."—*Bulletin of A. M. S.*

—1957. 352 pp. 6x9.

\$6.00

## VORLESUNGEN ÜBER DIE THEORIE DER ALGEBRAISCHEN ZAHLEN

By E. HECKE

"An elegant and comprehensive account of the modern theory of algebraic numbers."

—*Bulletin of the A. M. S.*

"A classic."—*Mathematical Gazette.*

—1923. 264 pp. 5 1/2 x 8 1/2.

\$3.95

## INTEGRALGLEICHUNGEN UND GLEICHUNGEN MIT UNENDLICHVIELEN UNBEKANNTEN

By E. HELLINGER and O. TOEPLITZ

"Indispensable to anybody who desires to penetrate deeply into this subject."—*Bulletin of A.M.S.*

—With a preface by E. Hilb. 1928. 286 pp. 5 1/4 x 8.

\$4.50

## Grundzüge Einer Allgemeinen Theorie der LINEAREN INTEGRALGLEICHUNGEN

By D. HILBERT

—306 pp. 5 1/2 x 8 1/4.

\$4.50

## PRINCIPLES OF MATHEMATICAL LOGIC

By D. HILBERT and W. ACKERMANN

The famous *Grundzüge der Theoretischen Logik* translated into English, with added notes and revisions by PROF. R. E. LUCE.

"The best textbook in a Western European language for a student wishing a fairly thorough treatment."—*Bulletin of the A. M. S.*

—1950. xii + 172 pp. 6x9.

\$3.75

## GEOMETRY AND THE IMAGINATION

By D. HILBERT and S. COHN-VOSSEN

The theme of this book is *insight*. Not merely proofs, but proofs that offer *insight*—intuitive understanding—into *why they are true*. Not merely properties of the hyperboloid or of Pascal's hexagon, but insight into *why they have these properties*. In this wide-ranging survey, one of the world's greatest and most original mathematicians uses insight as both his technique and his aim. Both the beginner and the mature mathematician will learn much from this fascinating treatise.

Translated from the German by P. NEMENYI.

CHAPTER HEADINGS: I. The Simplest Curves and surfaces. II. Regular Systems of Points. III. Projective Configurations. IV. Differential Geometry. V. Kinematics. VI. Topology.

"A mathematical classic . . . The purpose is to make the reader *see and feel* the proofs."—*Science*.

"A fascinating tour of the 20th-century mathematical zoo."—*Scientific American*.

"Students . . . will experience the sensation of being taken into the friendly confidence of a great mathematician and being shown the real significance of things."—*Science Progress*.

"A glance down the index (*twenty-five columns of it*) reveal the breadth of range:—

"Annulus; Atomic structure; Automorphic functions; Bubble, soap; Caustic Curve; Color problem; Density of packing, of circles; Four-dimensional space; Gears, hyperboloidal; Graphite; Lattices; Mapping; "Monkey Saddle"; Table salt; Zinc.

"*These are but a few of the topics . . .* The title evokes the imagination and the text must surely capture it."—*Math. Gazette*.

—1952. 358 pp. 6×9

\$6.00

## SQUARING THE CIRCLE, and other Monographs

By HOBSON, HUDSON, SINGH, and KEMPE

SQUARING THE CIRCLE, by Hobson. A fascinating and scholarly history of the number  $\pi$ .

RULER AND COMPASSES, by Hudson. "An analytical and geometrical investigation of how far Euclidean constructions can take us. It is as thoroughgoing as it is constructive."—*Sci. Monthly*.

THE THEORY AND CONSTRUCTION OF NON-DIFFERENTIABLE FUNCTIONS, by Singh. I. Functions Defined by Series. II. Functions Defined Geometrically. III. Functions Defined Arithmetically. IV. Properties of Non-Differentiable Functions.

HOW TO DRAW A STRAIGHT LINE, by Kempe. An intriguing monograph on linkages. Describes, among other things, a linkage that will trisect any angle.

"Intriguing, meaty."—*Scientific American*.

—388 pp. 4½×7½.

Four vols. in one \$3.25

## SPHERICAL AND ELLIPSOIDAL HARMONICS

By E. W. HOBSON

"A comprehensive treatise . . . an up-to-date handbook of spherical harmonics . . . and the standard reference in its field."—*Bulletin of the A. M. S.*

—1930. 512 pp.  $5\frac{3}{8} \times 8$ . Orig. pub. at \$13.50 \$6.00

## DIE METHODEN ZUR ANGENÄHERTEN LÖSUNG VON EIGENWERTPROBLEMEN IN DER ELASTOKINETIK

By K. HOHENEMSER

—(Ergeb. der Math.) 1932. 89 pp.  $5\frac{1}{2} \times 8\frac{1}{2}$ . Orig. pub. at \$4.25. \$2.75

## ERGODENTHEORIE

By E. HOPF

—(Ergeb. der Math.) 1937. 89 pp.  $5\frac{1}{2} \times 8\frac{1}{2}$ . \$2.75

HUDSON, "Ruler and Compasses," see Hobson

## THE CALCULUS OF FINITE DIFFERENCES

By CHARLES JORDAN

" . . . destined to remain the classic treatment of the subject . . . for many years to come."—*Harry C. Carver, Founder and formerly Editor of the ANNALS OF MATHEMATICAL STATISTICS.*

—1947. Second edition. xxi+652 pp.  $5\frac{1}{2} \times 8\frac{1}{4}$ . Orig. pub. at \$8.00. \$6.00

## THEORIE DER ORTHOGONALREIHEN

By S. KACZMARZ and H. STEINHAUS

The theory of general orthogonal functions. *Mono-grafje Matematyczne*, Vol. VI.

—304 pp.  $6 \times 9$ . \$4.95

KÄHLER, See Blaschke

## DIFFERENTIALGLEICHUNGEN: LOESUNGSMETHODEN UND LOESUNGEN

By E. KAMKE

Everything possible that can be of use when one has a given differential equation to solve, or when one wishes to investigate that solution thoroughly.

PART A: General Methods of Solution and the Properties of the Solutions.

PART B: Boundary and Characteristic Value Problems.

PART C: Dictionary of some 1600 Equations in Lexicographical Order, with solution, techniques for solving, and references.

"A reference work of outstanding importance which should be in every mathematical library."

—*Mathematical Gazette.*

—3rd ed. 1944. 692 pp.  $6 \times 9$ . Orig. publ. at \$15.00 \$9.50

KEMPE, "How to Draw a Straight Line," see Hobson

## GROUP THEORY

By A. KUROSCH

Translated from the second Russian edition and with added notes by PROF. K. A. HIRSCH.

A complete rewriting of the first, and already famous, Russian edition.

*Partial Contents:* PART ONE: The Elements of Group Theory. Chap. I. Definition. II. Subgroups (Systems, Cyclic Groups, Ascending Sequences of Groups). III. Normal Subgroups. IV. Endomorphisms and Automorphisms. Groups with Operators. V. Series of Subgroups. Direct Products. Defining Relations, etc. PART TWO: Abelian Groups. VI. Foundations of the Theory of Abelian Groups (Finite Abelian Groups, Rings of Endomorphisms, Abelian Groups with Operators). VII. Primary and Mixed Abelian Groups. VIII. Torsion-Free Abelian Groups. Editor's Notes. Bibliography.

Vol. II. PART THREE: Group-Theoretical Constructions. IX. Free Products and Free Groups (Free Products with Amalgamated Subgroup, Fully Invariant Subgroups). X. Finitely Generated Groups. XI. Direct Products. Lattices (Modular, Complete Modular, etc.). XII. Extensions of Groups (of Abelian Groups, of Non-commutative Groups, Cohomology Groups). PART FOUR: Solvable and Nilpotent Groups. XIII. Finiteness Conditions, Sylow Subgroups, etc. XIV. Solvable Groups (Solvable and Generalized Solvable Groups, Local Theorems). XV. Nilpotent Groups (Generalized, Complete, Locally Nilpotent Torsion-Free, etc.). Editor's Notes. Bibliography.

—Vol. I. 1955. 271 pp. 6x9.

\$4.95

—Vol. II. 1956. 308 pp. 6x9.

\$4.95

## FOUNDATIONS OF ANALYSIS

By E. LANDAU

"Certainly no clearer treatment of the foundations of the number system can be offered. . . . One can only be thankful to the author for this fundamental piece of exposition which is alive with his vitality and genius."—*J. F. Ritt, Amer. Math. Monthly.*

—1950. 6x9.

\$3.50

## HANDBUCH DER LEHRE VON DER VERTEILUNG DER PRIMZAHLEN

By E. LANDAU

To Landau's monumental work on prime-number theory there has been added, in this edition, two of Landau's papers and an up-to-date guide to the work: an Appendix by Prof. Paul T. Bateman.

—2nd ed. 1953. 1,028 pp. 5 1/2x8 1/2.

Two vol. set \$17.50

## ELEMENTARE ZAHLENTHEORIE

By E. LANDAU

"Interest is enlisted at once and sustained by the accuracy, skill, and enthusiasm with which Landau marshals . . . facts and simplifies . . . details."

—*G. D. Birkhoff, Bulletin of the A. M. S.*

—1927. vii + 180 + iv pp. 5 1/2x8 1/4.

\$3.50

## DIFFERENTIAL AND INTEGRAL CALCULUS

By E. LANDAU

Landau's sparkling *Einführung* in English translation. Completely rigorous, completely self-contained, borrowing not even the fundamental theorem of algebra (of which it gives a rigorous elementary proof), it develops the entire calculus including Fourier series, starting only with the properties of the number system. A masterpiece of rigor and clarity.

—1950. 372 pp. 6x9.

\$6.00

## VORLESUNGEN ÜBER ZAHLENTHEORIE

By E. LANDAU

The various sections of this important work (Additive, Analytic, Geometric, and Algebraic Number Theory) can be read independently of one another.

—Vol. I, Pt. 2. \* (Additive Number Theory) xii + 180 pp. Vol. II. (Analytical Number Theory and Geometrical Number Theory) viii + 308 pp. Vol. III. (Algebraic Number Theory and Fermat's Last Theorem) viii + 341 pp. 5 1/4 x 8 1/4. \* (Vol I, Pt. 1 is issued as *Elementary Number Theory*.) Originally publ. at \$26.40  
Three vols. in one \$14.00

## ELEMENTARY NUMBER THEORY

By E. LANDAU

The present work is a translation of Prof. Landau's famous *Elementare Zahlentheorie*, with added exercises by Prof. Paul T. Bateman.

PART ONE. Foundations of Number Theory. I. Divisors. II. Prime Numbers, Prime Factorization. III. G.C.D. IV. Number-theoretic Functions. V. Congruences. VI. Quadratic Residues. VII. Pell's Equation. PART TWO. Brun's Theorem and Dirichlet's Theorem. PART THREE. Decomposition into Two, Three, and Four Squares. I. Farey Fractions. II. Dec. into 2 Squares. III. Dec. into 4 Squares. IV. Dec. into 3 Squares. PART FOUR. Class Numbers of Binary Quadratic Forms. II. Classes of Forms. III. Finiteness of Class Number. IV. Primary Representation... VI. Gaussian Sums... IX. Final Formulas for Class Number.

EXERCISES for Parts One, Two, and Three.

—1958. Approx. 250 pp. 6x9.

\$4.95

## GRUNDLAGEN DER ANALYSIS

By E. LANDAU

The student who wishes to learn mathematical German will find this book ideally suited to his needs. *Less than fifty German words* will enable him to read the entire book with only an occasional glance at the vocabulary! [A complete German-English vocabulary has been added.]

—Orig. publ. at \$4.00.

\$2.95

## EINFÜHRUNG IN DIE ELEMENTARE UND ANALYTISCHE THEORIE DER ALGEBRAISCHEN ZAHLEN UND DER IDEALE

By E. LANDAU

—2nd ed. vii + 147 pp. 5 1/2 x 8.

\$2.95
